DR. ROBERT BATTEY, of Rome, Ga., followed, and presented the claims of iodized phenol as a remedy to be used in intra-uterine medication. He applied it by means of an applicator and cotton.

DR. J. MARION SIMS, of New York, without discussing directly the subject of intra-uterine medication, thought that most of the cases reported by Dr.

Batthey could have been cured much quicker by other means.

DR. ISAAC E. TAYLOR, of New York, referred to the same method of treatment, for what had been called incurable uterine catarrh, as that mentioned by Dr. Sims; and Dr. W. T. HOWARD, of Baltimore, regarded accuracy in diagnosis as of the greatest importance in cases in which intra-uterine medication was suggested, for the symptoms might depend on conditions that could be removed or corrected, and thus avoid its necessity. For the condition known as fungoid degeneration, he coincided in the use of the curette in preference to intra-uterine medication. If the internal os was sufficiently dilated, uterine injections might be used, but they should not be trusted to a nurse.

DR. FORDYCE BARKER, of New York, advocated intra-uterine medication. With regard to intra-uterine injections, he looked upon them as being dangerous when the cervical canal and body of the uterus were nearly normal in size; but when the uterus was enlarged, as after abortion or full labor, it was perfectly tolerant of injections into its cavity. The physician should give them himself. He then referred to classes of cases in which intra-uterine medication was more successful than any other means that could be adopted.

DR. JOHN BYRNE, of Brooklyn, thought that the secret of success in the use of intra-uterine medication was in the accuracy of diagnosis, not only with regard to the condition of the uterus, but more especially as to the question of etiology. The further the departure of the uterus from the normal to the pathological standard, the more tolerant it became of all medication and of all interference. That conclusion he had reached after an experience extending over fifteen years and injecting the uterus more than two thousand times. With reference to injecting the uterus, however, he had long since abandoned it except after using the curette, when he washed the cavity out with salt water, *being sure that the fluid had a good return.*

DR. PAUL F. MUNDÉ, of New York, did not use intra-uterine injections, although he resorted to intra-uterine medication by means of an applicator.

DR. WM. GOODELL, of Philadelphia, remarked that within the last few years he had been treating uterine diseases by means of intra-uterine medication with a great deal more satisfaction than formerly. With reference to intra-uterine injections, however, if the womb was positively diseased the cervical canal would be patulous, and there was no harm in throwing fluid into the cavity; but if there was doubt, the use of the measure might better be postponed.

DR. NATHAN BOZEMAN, of New York, was not entirely opposed to intra-uterine medication, but regarded the most important step to be, first, to correct the displacement which was almost always present in certain cases, such as uterine catarrh.

DR. H. P. C. WILSON, of Baltimore, advocated intra-uterine medication, and thought the chief danger arose from too much medication and too free and improper manipulation. He had abandoned injections into the cavity of the uterus.

DR. THADDEUS REAMY, of Cincinnati, treated the cavity of the uterus by medication, but he never employed injections in the non-puerperal uterus. He dilated the cervix and used an applicator.

THE PRESIDENT entertained the view that while intra-uterine medication above the os internum was, in many cases, exceedingly beneficial, it was, as a general rule of practice, one much more honored in its

breach than in its observance. He, however, looked upon intra-uterine antiseptic injections in puerperal fever as the great sheet-anchor of the physician, by whom only they should be administered.

Correspondence.

THE ESMARCH BANDAGE IN STRAPPING THE TESTICLE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Permit me through your columns to call the attention of the profession to the use of Esmarch's bandage as a substitute for adhesive plaster in strapping the testicle after epididymitis or in chronic orchitis. A bandage of pure rubber three-quarters of an inch wide and five feet long is easily applied, keeps in position well, and exercises a uniform and general compression such as is unattainable by any other method. In applying it, the fact that each additional thickness of bandage greatly increases the pressure should be kept in mind, and the whole placed with the exercise of but little tension, as the action of the bandage is, so to speak, cumulative. In covering in the bottom of the testis the turns should be made as in artistically bandaging the head, skull-cap fashion, the adhesion of the rubber surfaces rendering the operation easy.

STUART ELDRIDGE, M.D.,

Surgeon to General Hospital, Yokohama.

YOHOKAMA, JAPAN, Sept. 2, 1879.

CAUSE OF SUDDEN DEATH IN THORACENTESIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—By accident I omitted to see the number of the RECORD for August 23d, and thus, until yesterday, was unaware that my note on thoracentesis had been honored by a double commentary.

In regard to that made by Dr. Beverley Robinson there is little to say, since the doctor takes pains to show that he really accepts some form of the theory that I advocated; at least to the extent of attributing *death during the operation* to a cardiac rather than to a pulmonary origin. The statement, however, that "death occurs by syncope," is not as precise as that I endeavored to formulate, since the point at issue was to determine *how* the thoracic conditions occasioned by the operation could become a cause of the syncope which necessarily precedes death.

The note of Dr. Van Santvoord contains a valuable addition to the descriptions of the events which follow the sudden aspiration of fluid from the pleural cavity. I did not mention the aspiration of venous blood which unquestionably, according to the theory, should occur. But it is evident that *this is consequent upon the exaggerated diastole of the heart*, the very phenomenon upon which I insisted as the immediate consequence of restored mobility to the chest-walls, for the blood cannot pass to the "imperfectly expanding lung" except by passing through the abnormally expanded heart.

Dr. Van Santvoord justly calls attention to the fact that, at the moment the long immobilized chest-wall first begins to move, the compressed lung is often unable to expand sufficiently to fill the restored thoracic cavity. The aspirating force of the outward-moving

thorax is therefore directed with abnormal intensity upon the heart. In other words, the negative pressure to which the heart is habitually subjected during inspiration, and by which its own diastolic movement is reinforced, is abnormally increased after rapid thoracentesis: 1st, because a part of the chest-wall begins to move which for a long time had been motionless; 2d, because the aspiration is so ineffectual on the lung. But when the diastole of the heart is exaggerated, and its cavities are enlarged, then more blood is aspired into it, both from the pulmonary and systemic veins. Without such previous cardiac dilatations the effect of thoracic suction could not be transmitted to the veins, nor could atmospheric pressure force blood into a heart contracted as in prolonged systole.

Dr. Van Sautvoord's observation, therefore, far from contradicting the statement of my note, serves to bring out an interesting additional confirmation of the views therein expressed, namely, that the first effect of the operation was liable to be an exaggerated diastole of the heart; and Dr. Van Sautvoord emphasizes the fact I omitted to notice, namely, that this liability was great in proportion to the delay experienced in the expansion of the previously compressed lung.‡

The reason that the amount of force stored in the cardiac ganglia needs to be taken into consideration is this. As there are about four pulsations or complete cardiac revolutions for every inspiration, we find the inspiratory force exerted, not merely during the diastole of the heart, which it favors, but during the systole, whose force it diminishes. Now, in estimating the effective work of the heart, we calculate especially that of the systole, and as inspiration is antagonistic to this, the pressure it determines is called negative—an expression, I need hardly say, not original with myself. If, in the circumstances under consideration, the force of the systole were increased in proportion to that of the diastole, no harm would ensue. For whatever excess of blood should have been aspired to the heart during one part of the inspiratory movement would be thrown out again before that movement had terminated. This is what happens under the influence of quinine, which also increases the diastole of the heart directly—but indirectly the systole, which becomes strengthened to correspond. After thoracentesis, however, while such powerful agencies are at work to increase diastole, there is no agency in operation to increase the systole; and, as I must beg leave to repeat, since the operations of nervous ganglia are predominantly regulated by habit, there is, during a chronic pulmonary effusion, such a diminution in the respiratory movements of the thorax that the cardiac ganglia must have been obliged to *expend less force than usual to antagonize them*. The question whether or no the heart has had to struggle against greater obstructions does not touch upon this point, which seems to me too obvious for question, and the simple collapse of the lung, more or less deprived of air, does not offer a formidable obstruction any more than do unexpanded fetal lungs. Dr. Van Sautvoord thinks that if there has been no cyanosis, the respiratory movements must have been, on the whole, normally powerful during the effusion, the exaggerated expansion of the sound side compensating for the immobilization of the other. Setting aside the fact that impending cyanosis so often constitutes the very indication for the operation, I would suggest that when it is not present it has been averted by exaggeration in the frequency of respiration. The compensation is rarely complete, except in the latent

cases of hydrothorax; hence the characteristic dyspnoea. But increased *frequency* of respiration, which enables more oxygen to have access to the blood, is itself a proof of diminished *force* in each respiratory movement, hence diminished aspirations on the heart. By this, therefore, I find myself again brought round to the original thesis, that the cause of death is exaggerated cardiac diastole.

I am, sir, yours truly,

M. PUTNAM-JACOBI.

110, WEST THIRTY-FOURTH STREET.

OPIUM HABITUATION.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The very interesting case of opium habituation, detailed by Dr. W. F. Hutchinson in the RECORD of to-day, prompts me to offer some comments on the various points therein brought forward.

The complex manifestations so strongly symptomatic of direct cerebral disturbance presented at the initial visit, but which, on fuller investigation, were found largely due to a course not at first appreciated, suggest the propriety of careful query in all obscure cases of neurotic disorder as to the probability of this factor in causation—a point of importance in view of the prevalence of opiate indulgence, the facility with which it can be carried on in secret, and especially as no radical result for good can be looked for in such instances without an appreciation of this element, and treatment specifically directed thereto.

A study of the clinical history given impresses me with the belief that the varied nervous symptoms were due to a combined action of neurasthenia proper and the opiate tincture; for, with an experience covering several years, and cases in which the narcotic addiction was decidedly in excess, both as to time and quantity, I have never observed some of the signs of disturbed nervous action here presented: but "six years of almost constant pain and general nerve-exhaustion," augmented by the pernicious effect of several ounces laudanum daily taken, would be quite sufficient to provoke profound nerve-disturbance with an exceedingly complicated symptomatology.

The etiology of this case is strongly suggestive. Ten drops of laudanum for post-partum pain—repeated at first with professional sanction, doubtless; later, self-administered, unconscious of peril and unwarned by medical adviser—paved the way for years of misery, which, it is safe to say, might have been avoided, or at least greatly lessened, by the exercise of proper care in this direction, and affords further proof of the danger attending incautious opium-taking in broken-down nervous females. How many women are to-day sitting in a similar shadow is beyond our knowing; but it is known that they swell largely the ranks of opium habitués, and that a large proportion of the deviations from health which induce the use of some form of opiate, are dependent on disorders peculiar to their sex. My personal experience is entirely confirmatory of this statement, and, in conversation with an eminent gynecologist of this city, he assured me his observations were strikingly in the same direction, and that he always strongly inculcated the virtue of extreme caution in the use of opiates in uterine derangements. When this laudable example is appreciated and put in practice by other obstetrical teachers and their pupils, many mothers and daughters of the future will have cause to be grateful for an exemption from one phase of suffering denied their sisters of to-day. The fact cannot be too strongly in-

aided upon that the great majority of opium habitués—among us, at least—are such not from a mere *vicious* initial indulgence, but because their first acquaintance dates from its more or less direct professional employment, and afterwards continued for lack of that care and caution from medical advisers which it is their province and their duty to give.

The substitution of chlorodyne was an excellent idea as tending to break the chain of *habit*, which becomes of some importance where the opiate withdrawal is prolonged for weeks or months. Opium habitués, in many cases, come to attach no little importance to the fact that they know just what they are taking—they associate a certain cause and effect. Change the form of their opiate—of course without their knowledge of the substitute—break them away from the idea that they *must* have this or that, and the mental impression is undoubtedly for good. In this fact, aided by gradual decrease, lies largely the secret of whatever success belongs to the horde of vampires throughout the country who specially prey on such unfortunates. Besides, laudanum, even in chronic takers, sometimes causes gastric disturbance, which will entirely disappear if morphia be substituted; and as the latter enters into the composition of chlorodyne, this may have had something to do with the subsidence of vomiting in Dr. H.'s case which had become persistent.

There is no question in my mind as to galvanism being the main agent in cure. Something is to be placed to the credit of time and the very gradual opium decrease—four months being occupied in recovery; but that the former deserves the principal share is proven by the fact that in eight weeks, during which no opiate reduction was made, the patient had much improved, and that then withdrawal was begun and continued, which before had failed owing to the prostrated nervous condition and the lighting up of severe reflex irritation when any attempt was made. After that time, a doubly good influence was exerted, going steadily forward to health. It may not be amiss to note in this connection that, in a letter received from Dr. Hutchinson since his case was reported, he says: "I regard the quality of current in these cases of prime importance. It should be from a series of *large, constant* cells, . . . absolutely constant—as I have found the smallest current variations occasionally productive of serious trouble." And Dr. Anstie, from a somewhat similar standpoint, wrote: "The first quality that must be absolutely required in a battery that is to be used for this purpose is, that it shall deliver its current with as little as possible variation of tension—in fact, that it shall be *constant*, and not merely *continuous*." Thus employed, we have a remedy exerting a strongly marked tonic effect on the nervous system, and consequent vitalizing action on volition up to that point where it can reassert itself and bring into play a power for good that nothing so prostrates as opium.

The success in this case of gradual opiate decrease along with treatment directed to restoring impaired nerve-tone, proves the virtue of persistent continuance in well-doing, and is sufficient answer to those professional skeptics who assert that "tapering off" will not result in cure. In many cases it will not; the weeks and months required exhausting patients' patience, and unless under professional supervision, making them very apt to abandon the effort. But even where time is an object of importance, and a prompt process is desired, entire and immediate withdrawal is scarcely ever advisable, entailing as it does severe distress of mind and body, both unwise

and inhumane, inasmuch as the good result can certainly and speedily be secured by a method of treatment largely free from such suffering, the plan of *preliminary sedation*—a happy medium between the two extremes—to which I have referred in a former paper. This, which has been pronounced "the most sensible and scientific," offers in suitable cases advantages superior to any of which I have knowledge, and must be observed or experienced to be appreciated as it deserves.

In the case under consideration the treatment was eminently judicious, and patient and physician alike are to be congratulated on the brilliant result.

J. B. MATTISON, M.D.

BROOKLYN, Aug. 9, 1879.

DESTRUCTION OF THE CEREBRO-SPINAL CENTRES.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In your issue of Sept. 13, 1879, Dr. Thomas W. Poole has published an article in which he calls attention to an assumed fallacy in the generally received theory that the effect of destruction of the cerebro-spinal centres is to produce vaso-motor paralysis, and, consequent thereon, arterial relaxation. His objection is based on experiments made by himself on rats, kittens, puppies, and frogs, whose spinal cord and cerebral ganglia he had destroyed by opening the upper part of the spinal canal and breaking up the organs in question with an instrument introduced through this opening. The result of these experiments was "that, so far from the arteries being relaxed or dilated with blood, we invariably found them empty, pale, and contracted; while, in marked contrast, we as uniformly found the entire venous system distended, and its swollen tubes dark blue from the quantity of blood contained in them. We found this fact less palpably shown in frogs," etc. "But in the mammalian subjects the emptiness of the *aorta and its chief branches*, the smallness and paleness of the *iliac arteries* contrasted with the corresponding dark and swollen veins," etc. (italics the present writer's). From this quotation it is apparent that Dr. Poole has confined his observations to the condition of the *great vessels* ("aorta and its chief branches," "iliac arteries"). Now, these large vessels, it is well known, are virtually elastic tubes with no contractile power whatever. Muscular cells are entirely absent in the aorta near the heart (Eberth, in Stricker's Manual of Histology, Wm. Wood & Co.'s translation, 1872, page 196), and insignificant in number in the other great arterial trunks. Consequently the paleness and "contraction" (*i. e.*, retraction) of these vessels are not considered *in themselves* an index of vascular contraction or relaxation. They are simply distended or relaxed, like so much rubber tubing, according as there is or is not a distending force applied to them.

The contractile fibres are to be found in considerable numbers only in the smaller arteries and arterioles, and here it is—not in the large vessels at all—that we should look for the effect of nerve-action on the vessels.

If the small arteries and arterioles were paralyzed, it is perfectly obvious that the passage of the blood through them into the veins would be easier than if they were strongly contracted. If, then, the left heart and arteries are, in reality, as we suppose is generally assumed, emptied by the final contraction of the heart, and in the case of the great vessels the final

retraction of their elastic walls, what we would expect to find in cases of vaso-motor paralysis and consequent relaxation of the contractile arteries, is exactly what Dr. Poole *did* find, only, if possible, more pronounced. The obstructions to the performance of this final contraction and retraction being more than ordinarily small, the work would be performed, if possible, with more than ordinary completeness. If the small arteries had contracted, as Dr. Poole has assumed, the blood would have been dammed back in the great vessels and heart; obviously quite a different condition of affairs would rationally, in accordance with the above-mentioned theory, be expected, *i. e.*, engorgement of these viscera with the dammed back blood.

It is not apparent, however, from Dr. Poole's paper, that the great vessels were, in his experiments, found to be any smaller or paler than they would have been in death from any other cause. The supposition that the left heart and arteries are emptied at death by the final contraction of the heart, the final retraction of the elastic vessels, and a final contraction of the muscular arteries, has always seemed to us very unsatisfactory. That the left ventricle can empty itself by its final contraction is perfectly conceivable. That elastic tubes which have only a retractile power, and which cannot reduce their lumen below a certain fixed diameter can empty themselves is perfectly inconceivable. That the small arteries, being provided with organic muscular fibres, may possibly reduce their lumen to zero by the gradual contraction, characteristic of that variety of muscular fibre, may be possible for anything the writer knows to the contrary. Some force, other than any which this supposition supplies, is very obviously necessary to explain the emptying of the great non-contractile vessels. This force has been supposed to exist in a suction exercised by the right heart and muscular arteries. How a soft, flabby, muscular bag is to actively dilate and produce any such effect we cannot conceive. How hollow muscular cylinders by slowly reducing their calibre to zero, even supposing that a vermicular motion like that which the intestines undergo, can produce any such effect, is equally incomprehensible. The only available hypothesis remaining seems to us the theory advanced by Prof. W. H. Draper in his "Human Physiology" (1856, page 130, etc.), that "capillary attraction" is a force in the circulation.

Dr. Draper points out the fact that in plants we have circulation without any organ of propulsion (heart). The agent which induces this circulation is probably the affinity of the vegetable cells for the nutriment contained in the sap. When the sap reaches the leaf it undergoes chemical changes which, together with the loss of substances given out to the cells, destroys this affinity or attraction. The cells then attract the fresh sap below that whose virtues are exhausted, so that this fresh supply is drawn upward and the effete and used-up sap is displaced. Similarly, Dr. Draper argues, an attraction may exist between the arterial blood and the tissues which need the oxygen and other nutriment which the blood brings to them. This nutriment once delivered, and the excrementitious matter (carbonic acid and possibly other effete material) having been substituted in its place, this attraction may cease and the blood become venous, may be hurried on by that which is coming behind and which is being drawn toward the tissues by the attraction existing between it and them.

It may be true that this force is too insignificant to be of moment during life when the heart is in full vigor. But may it not be by this force, this "capil-

lary attraction" so called, that, just after the cessation of the heart-beat, the blood is drawn, very gradually perhaps, from the arteries and heaped up in the veins? That this process is, as a matter of observation, slow, would be inferred from the following quotation from Dr. W. B. Carpenter's "Principles of Physiology," 5th Am. Ed., p. 334 (alluded to by Dr. Poole in another connection): "The contraction of the arterial tubes" (*i. e.*, just after death), "is so great as to produce for the time a great diminution in their calibre, and this, doubtless, contributes to the passage of the blood from the arteries into the venous system, which almost invariably takes place within a few hours after death" (*italics* ours). Dr. Poole, we would remark parenthetically, refers to this sentence as "a further proof" of his theory. It seems to us hardly justifiable to assume an identity between this post-mortem phenomenon and vital contraction. The rigidity of the voluntary muscles after death, which is one and the same process as the "contraction" of the involuntary muscular coats of the arteries after death, is very unlike the contraction of these muscles during life. One might just as rationally call rigor mortis and tetanus one and the same thing.

It may be objected that the supposition of "capillary" attraction or tissue attraction as a force in the circulation of the blood, is somewhat transcendental and not proven. It is at least supported by strong analogy; accords perfectly with all observed facts as far as the writer knows them, and is far less objectionable, it seems to us, than to suppose that the last feeble throb of a dying heart, and the retraction of a system of elastic tubes following this last puny effort, aided by a slow contraction of the muscular arteries, are capable of driving several ounces of blood through and out of this same system of elastic tubes into the veins, especially as this slow contraction of the muscular arteries, unless, indeed, a vermicular motion similar to that in the intestines is assumed to take place, must, in driving the blood out of the contracting vessels, force it backward into the great vessels as well as forward into the capillaries and veins, there being no provision in their anatomical structure against regurgitation.

Some light on this subject from the physiologists is desirable.

Dr. Poole thinks it "absurd" to believe that "a little brandy," a "stimulant" which "produces flushing of the face" can produce "paralysis" of anything. Now, any organ is increased in functional activity by having sent or admitted to it an increased supply of arterial blood, if we rightly recall prevailing theory on the subject. If nature chooses to accomplish this by causing relaxation of certain muscular fibres in the walls of certain arteries, we can see no intrinsic absurdity in the process, any more than we can in the relaxation of the vesical and anal sphincters during the active physiological processes of urination and defecation. Relaxation of a muscle is not necessarily paralysis. The term *paralysis* implies a more or less permanent lesion of a nerve-centre (which interferes with the generation of nerve-force, or with the perception of an irritation transmitted from the periphery to the nerve-centre) or of a nerve-trunk or nerve-periphery (which interferes with the transmission of nerve-force to the tissue-elements to be acted on), or with the conduction of an irritation from the periphery to the nerve-centre. The general relaxation of the voluntary muscular system of a healthy man during profound sleep is *not* general paralysis. The condition of the muscular arteries in the face of a man flushed by brandy is more properly spoken of as relaxation rather than as paralysis.

That Dr. Poole may be correct in his belief that muscular contractility is inherent in muscular fibre, and independent of nerve influence, seems probable enough, and the supposition is one which, as he intimates, is not original with himself.

How soft, hollow muscular cylinders can actively dilate themselves, is a mechanical problem which must be worked out by its originators before they can reasonably insist on its acceptance as a fact by others. It has been explained, we are aware, by the fact that the longitudinal muscular fibres contract, and as a result of contraction become shorter and increased in diameter. As a result of this increase in diameter, they are said to shoulder each other away from the centre of the tube (see figures), and so increase its lumen. In the gross caricature which we have

drawn, this may seem plausible enough. A single glance at a microscopic section of a real artery will demonstrate the feebleness, to say the least of it, of this hypothesis; yet it is the only one, as far as we know, which has been advanced on the subject.

It seems most plausible to us to assume that muscular fibre does possess an inherent power of contractility independent of nerve-action, and that nerve-force acts merely as an excitor or inhibitor of this inherent power. This we suppose to be the generally received theory. Very truly yours,

R. VAN SANTVOORD, M.D.

66 WEST ELEVENTH STREET, SEPT. 19, 1879.

COMPOUND GELATINE MEDICATED TENTS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Every practitioner must at times have desired to treat diseased mucous surfaces by a method less abrupt and less transient than the application of medicated solutions, by syringe, or spray, or sponge.

This feeling induced me in the course of the last winter to employ gelatine as a vehicle which, by slow solution in the natural fluids, should give a continuous supply of the agent employed to treat the morbid conditions.

The first product of this effort, though very crude in form, showed that the idea was valuable, and through the very careful and prolonged studies of Mr. Otto Boetcher, of the firm of Spangenburg & Boetcher, the profession now may have the opportunity of determining the range of its useful application.

Mr. B. will furnish them with tents or bougies, medicated to their taste; the methods by which he has reached the present perfection of product not being known to me.

These bougies are of the size of a rye straw—6 to 8 mm.—are smooth of surface, and dissolve in the mucous channels in from one-half to two hours, leaving nothing but fluid bearing the medicament employed.

They are, when kept in glass vials, as pliable and smooth as a French urethral bougie; but if exposed to ordinary dry air become as rigid as whalebone rods in an hour or two. If then returned to the bottle they become soft again.

I have employed them, *first*, in the nasal cavities, being able thus to direct the application much more accurately to a limited area than by injection or spray; *second* (and it is for this purpose that they will be found most valuable), in the cervical canal and in the

cavity of the corpus uteri; *third*, in the female urethra; *fourth*, in the rectum.

Those which I first used in the nasal passages were medicated with sulphate of zinc and tannin and carbolic acid.

The uterine tents are for the most part medicated with iodine or iodoform. Those of iodine contain 6 per cent. by weight of the pure crystal of iodine. Those of iodoform contain 25 per cent. by weight.

I have found no method of treating the endometrium with these substances so safe, so easy, so painless, and so efficient as this. The tent, two to two and a half inches in length, is taken in a pair of uterine forceps, dipped for a moment in water, and then pushed through a speculum into the os uteri. Its surface is so well lubricated, and it is so pliable and yet so firm, that it will be readily pushed on to the fundus uteri, and may be left there to dissolve *in situ*.

This I constantly do, and think I have cured catarrhs thereby in less time, and much more thoroughly, than by the cotton-wrapped application.

The gynecologist will ask: Do you not have uterine colic sometimes? I have not had a case in which the patient complained of any discomfort from the placing of the tent or afterward. They do complain that iodoform makes them disagreeable and unfragrant, but that is all so far as I know.

Dr. H. T. Hanks, who has made large use of them, tells me that he has had some colic in two cases out of several score.

Iodine and nitric acid, as applications to the endometrium, have, in both English and American practice, nearly superseded all other agents. Their great value is endorsed by almost every gynecologist. To them, and through the convenience of this method, iodoform will be added.

The iodoform tent has been most largely used by Dr. Hanks; the iodine by myself, for chronic endotrachelitis, endometritis, salpingitis, erosions, hemorrhages, hyperplasias, etc.

Aside from these, Mr. Boetcher has prepared tannin, tannin and iodoform, tannin and zinc, and various other tents, and will prepare any which he may be desired to supply, on short notice.

W. M. CHAMBERLAIN, M.D.

68 WEST FORTIETH STREET, SEPT. 22, 1879.

Obituary.

SETH WESTON WILLIAMS, A.B., M.D.,

NEW YORK.

DR. SETH W. WILLIAMS, son of the Hon. Chas. Williams, of Nashua, N. H., died after an illness of one week, on the morning of September 20th, at the Preble House, in Portland, Maine, of softening of the brain. The disease, as the autopsy showed, was limited to the right lobe of the cerebellum and corresponding side of the fornix.

When taken sick, Dr. W. was away from home spending his vacation at the seaside, and not until a day or two after the commencement of his illness did he recover consciousness sufficiently to make known his name or residence. Throughout the remainder of the sickness, however, he retained his mental faculties, and, although surrounded by the ablest physicians of New York and Portland, kept prescribing for himself and making frequent diagnoses of his condition.

The deceased was a graduate of the Nashua High School and of Phillips Academy, Andover. He en-

tered Yale in 1868, and, after remaining, on account of feeble health, one year away from college, received the degree of Bachelor of Arts. After graduation, Dr. W. travelled for several months in Europe and the Holy Land. On his return to America he began the study of medicine in the office of Dr. Jas. R. Wood, of New York, and received in the spring of 1876, from the Bellevue Hospital Medical College, the degree of Doctor of Medicine and the Flint prize for excellency in physiology. The same year he went abroad a second time, and, under the direction of Prof. Salsbach, of Heidelberg, pursued a course of study in the German classics. In the fall of 1876 Dr. W. became interested in the study of pathological anatomy, which he pursued as a student of Prof. Virchow till the following year, when he returned to Heidelberg, to begin a course of special work with the microscope in the laboratory of Prof. Arnold.

After having acquired the knowledge for which he visited Europe, Dr. Williams returned to New York, and was admitted to Bellevue Hospital. He was assigned to the Third Medical Division, and would have been the house-physician of that institution after the first of October of this year. While performing his many and varied duties at the hospital he found time to prepare a most elaborate and exhaustive article on the "Etiology and Pathology of Pott's Disease," which was presented to the Faculty of the Bellevue Hospital Medical College, and was awarded the Sayre prize of \$200 for originality of research and clearness of thought.

The funeral services were held at the residence of his father, ex-Mayor Williams, at which the attendance of relatives and friends was very large.

Purity of thought and of action were the silent forces that drew about him a large number of friends. He endeavored to make his life one of usefulness, and seriously entertained the idea of becoming a missionary physician under the auspices of the American Board of Commissioners of Foreign Missions. An abiding faith in God and conscientiousness in the discharge of every duty, were the distinguishing traits of his character.

ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Sept. 21st to 27th, 1879.

WEBSTER, W., Major and Surgeon. Relieved from duty at Fort Warren, Mass., and assigned to duty as Post Surgeon at Fort Preble, Me. S. O. 167, Dept. of the East, Sept. 22, 1879.

FORWOOD, WM. H., Major and Surgeon. The leave of absence granted him from Headquarters, Dept. of the South, extended two months. S. O. 218, A. G. O., Sept. 20, 1879.

BREWER, J. W., Capt. and Asst.-Surgeon. Granted leave of absence for six months on surgeon's certificate of disability. S. O. 219, A. G. O., Sept. 22, 1879.

TREMAINE, W. S., Capt. and Asst.-Surgeon. So much of Par. 3, S. O. 195, Aug. 25, 1879, from A. G. O., as relates to him, is revoked. S. O. 220, A. G. O., Sept. 23, 1879.

KIMBALL, J. P., Capt. and Asst.-Surgeon. Having reported in person at these headquarters, assigned to duty at Ft. Sanders, Wyo. Ter. S. O. 82, Dept. of the Platte, Sept. 20, 1879.

TAYLOR, B. D., First Lieut. and Asst.-Surgeon. Granted leave of absence for three months, with permission to apply for an extension of one month. S. O. 222, A. G. O., Sept. 25, 1879.

List of Changes in the Medical Corps of the Navy for the week ending September 19, 1879.

September 15th.—Pd. Asst. Surgeon A. A. AUSTIN, detached from the Colorado and ordered to Navy Yard, Norfolk, vice Assistant Surgeon H. T. PERCY, detached and ordered to Coast Survey duty.

September 16th.—Pd. Asst. Surgeon F. ANDERSON, leave extended six months.

September 18th.—Surgeon J. W. COLES, ordered to hold himself in readiness for duty on U. S. S. Nipsic.

Surgeon G. F. WINSLOW, detached from the Wachusett, and to hold himself in readiness for duty on U. S. S. Vandalia.

Surgeon J. B. PARKER, detached from special duty and ordered to the Wachusett.

Asst. Surgeon Charles W. RUSH, detached from Naval Hospital, New York, and ordered to the Receiving Ship Colorado, New York.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending September 27, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Sept. 20, 1879.	0	8	41	1	38	13	0	0
Sept. 27, 1879.	0	31	31	3	18	35	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from September 24th to September 30th, inclusive, was 84, and the number of deaths that occurred was 42. The total number of new cases for this year to October 1st is 1351, and the total number of deaths, 451.

THE UNIVERSITY MEDICAL COLLEGE.—The introductory lecture of the regular winter course for 1879-80, was delivered on Tuesday evening, September 30th, at 8 o'clock, by Prof. John C. Draper, M.D., LL.D. Subject, "Medical Education."

THE COLLEGE OF PHYSICIANS AND SURGEONS.—The opening exercises of the seventy-third regular winter session of this institution took place on Wednesday evening, October 1st, at 8 o'clock. The introductory address was delivered by Prof. Henry B. Sands, M.D.

COLUMBIA VETERINARY COLLEGE.—The opening exercises of the second regular winter session took place on Wednesday evening, October 1st, at 8 o'clock. The introductory address was delivered by Prof. Thos. H. Hawkins, M.D., V. S.

THE BELLEVUE HOSPITAL MEDICAL COLLEGE.—The exercises at the opening of the regular course of lectures were held on Wednesday evening, October 1st, at 8 o'clock. An address was delivered by Prof. Austin Flint, and was followed by remarks by Prof. James R. Wood, Emeritus Professor of Surgery, and by Dr. Thomas H. Burchard, of the Alumni Association.

THE *American Journal of Electrology and Neurology* says that "in May last the New York County Medical Society admitted to membership a graduate of the New York Homœopathic Medical College."

Original Lectures.

THE
PRESENT STATE OF THERAPEUTICS.

AN ADDRESS

DELIVERED AT THE OPENING OF THE FIFTY-SIXTH COURSE
OF LECTURES IN JEFFERSON MEDICAL SCHOOL.

By ROBERTS BARTHOLOW, M.D., LL.D.,

PROFESSOR OF MATERIA MEDICA AND GENERAL THERAPEUTICS.

(Reported for THE MEDICAL RECORD.)

I HEARD, but a few years ago, a very able teacher, himself a Professor of Practice, declare that if the four great chairs of Anatomy, Surgery, Practice of Medicine, and Obstetrics were well filled in a medical school, it was of little consequence who occupied the others; and as for *Materia Medica* and Therapeutics, any old woman could teach that. His was the traditional old woman who knew how to prepare catnip, tansy, and similar teas, and on special occasions could administer castor oil—an amount of therapeutical knowledge sufficient now for the leaders of French medical practice, if we may credit some recent reports from Paris.

Scientific physicians have usually held therapeutics in small esteem, doubtless because it had small deservings. In Bichat's time it was a feeling of contempt, which found expression in his famous declaration: "*Materia Medica* is a shapeless mass of inexact ideas, of observations often puerile, of imaginary remedies, strangely conceived and fantastically arranged." No one possessed of any knowledge of the subject, could now, on examination of the therapeutics of that day, deny the justice of Bichat's denunciation. It was an incongruous mixture of empirical notions, based on the crude theories of various medical philosophies—partly humoralist, partly solidist, partly of the Italian contra-stimulant school. It embraced the mechanical and chemical theories of the great Boerhaave, the vitalistic mysticism and the expectant practice of Stahl, and the solidist theories of Hoffmann. The whole mass was hardly in advance of that condition of therapeutics against which were levelled the shafts of Montaigne, the jests of Molière, and the morbid fancies of Rousseau. In fact, it was not until the birth of modern physiology that scientific therapeutics became possible, and that epoch was at a period within the memory of men now living. It may seem almost incredible, but it is true, that any considerable body of scientific facts in therapeutics has been the product of the last twenty years—for scientific therapeutics must always follow the course of discovery in physiology. Even now, there must necessarily be two methods pursued in advancing the knowledge of therapeutics: the empirical or rational, and the physiological or scientific. The empirical method is based on the principle, as ancient as our art, that a remedy which has cured a case of disease must also cure analogous cases. The scientific method is the application of physiological research to ascertain the actions of medicines, and on this sure basis is predicated the use of remedies in the treatment of disease.

The inherent difficulties of the subject, it must be admitted, are in large part responsible for its tardy development. In part its slow progress is due to an unreasoning conservatism, which admits of but one

road to the acquisition of truth. Even now there are many so-called practical men who are disposed to sneer at physiological therapeutics, and to make themselves unhappy over achievements which experience can utilize, but has had no agency in accomplishing. They should reconcile themselves to the inevitable by the philosophy of the old Spanish proverb: *Let the miracle be done, though Mahomet do it.* They should be satisfied with the progress of truth, though they may not approve of the means by which that progress has been achieved.

But the most vehement reactionists are yielding to the force of therapeutical discovery accomplished by physiological methods.

Thus, one of the most eminent therapeutical authorities of our day has declared in a preface written so recently as October, 1874: "In the first edition of this work the author contended against the mischievous error of seeking to deduce the therapeutical uses of medicines from their physiological action. Continued study, observation, and reflection have tended to strengthen his convictions upon this subject, and to confirm him in the faith that clinical experience is the only true and safe test of the virtues of medicines." The same author, in another work on the same subject, after another five years of study, observation, and reflection, says, in a preface dated 1879: "Whenever it seemed possible, an attempt to apply the results of physiological experiment to therapeutical uses has been made; for although the two fields of inquiry may not be so organically connected as to render the former a guide to the latter, it is, nevertheless, true that a scientific explanation of the curative powers of medicines must be sought in the results of their experimental operation upon the animal functions."

No revolution of opinion could be more complete; no renunciation of heresy more absolute. In 1874 empiricism is the true guide, in 1879 physiological experiment. This, though somewhat sudden, is significant of a change which is taking place in the last strongholds of empiricism. Such a quotation must satisfy the doubts of all—and they are legion—who respect authority and are governed by its utterances.

I hope I shall not be misunderstood. Far be it from me to abate one iota of the just fame of the author whose works I have quoted, or to impute inconsistency in his opinions, or to cast doubts on the accuracy of his judgments. I quote his words to demonstrate the revolution which has taken place by the application of the modern, scientific methods, with results so convincing, that the deepest convictions from wide learning and extended experience are made to yield. Honor and praise rather to the honesty of him who can surrender his own cherished convictions rather than do violence to truth.

Revolutions do not go backward, and they are apt to be radical in medicine. Furthermore, it is surprising to what extent fashion rules current medical opinion and modes of practice. Do the leaders in medical thought take a certain direction, their followers pursue pell-mell. This is observable now in the revolution which has taken place with respect to empiricism in therapeutics, and in certain quarters there exists a disposition to ignore all that has been accomplished by it, and to rely exclusively on the physiological method. This extreme tendency ought to be resisted in so far as there is danger of putting aside some of our most valuable acquisitions. It is far wiser to possess us of every aid which either method can offer—to accept the scientific facts which an exact physiological research can contribute, and to retain and extend that knowledge, the truth of

which has been confirmed by the experience of generations of accurate observers. In fact, when we come to investigate the subject we find that the physiological method is not free from sources of fallacy, from contradictory observations, from conclusions that subsequent investigations show to be erroneous. I freely admit that it is less hampered and overgrown by errors and contradictions than is the empirical method, but there are uncertainties and confusion which ought, if possible, to be eliminated. The first step necessary is to have a clear conception of the sources of error, and I think we may spend a part of this hour very profitably in an attempt to measure them. The important question is: What are the difficulties in the way of right conclusions respecting the actions and uses of our remedies, especially their value in the treatment of disease?

We may certainly place foremost the imperfections of man—the limitation of our faculties. Then comes the absence of the necessary training, or its insufficiency, and the utter lack of power of logical analysis in many of those who occupy the position of authorities. These mental defects and faults of training can never be overcome. "In the conduct of life," says Mr. Mill, "wrong inferences and incorrect interpretations of experience, unless after much culture of the thinking faculty, are absolutely inevitable; and with most people, after the highest degree of culture they ever attain, such erroneous inferences are as frequent, if not more frequent, than are correct inferences correct interpretations of experience." Such being the case, it is not surprising that in a matter so beset with fallacies as the estimation of the curative power of a remedy, that there must be few qualified by natural powers, and by training for the task. The best equipped and most carefully trained intellect may not possess the power of observation; it may be unerring in the conclusions formed from the facts submitted, but the faculty of discernment, of seeing things as they exist may be deficient or inaccurate. That which Mr. Mill calls "mal observation," consists in "something that is not simply unseen, but seen wrong." With the best intentions, the purest conscientiousness, men making observations—trained observers—differ surprisingly in their accounts of events occurring on a particular occasion. A capital illustration of this fact has been afforded by the discrepant accounts from the observers of the corona and the solar protuberances. Observed with the same instruments under the same conditions, the various operators have differed widely, with the usual result of heated controversy. An ingenious theorizer has shown that the difference lay in the eyes of the observers: some were normal—some were astigmatic, myopic, etc. As in Turner's pictures, the artist's oddities appeared when he had lost somewhat his appreciation of the harmony of colors. Not long since Klein saw, in investigating the changes in typhoid, a minute organism which seemed to have an important relation to the genesis of this disease, and there was much enthusiasm expended over the discovery, but in a few months a terrible iconoclast disposed of the discovery at one blow, by showing that the supposed organism was nothing more than a bit of albumen, altered by the reagents used in making the preparation. How much easier to form accurate conceptions, and give correct descriptions of things submitted to the evidence of our senses, than the phenomena arising from occult processes in the human body. Unfortunately, many of those occupying the position of authorities, always discern that which their preconceived opinions led them to search for; other observ-

ers look at facts with vision tinted by what Mr. Spencer calls the "professional bias;" in a variety of ways, the thing is not simply unseen, but seen wrong. The salutary lesson which we learn from this is: we cannot be sure that the things which we suppose we see are actually before us, and the other and higher lesson of patient waiting and study of our supposed facts, and comparison of them with the facts of other observers.

If we observe correctly as to the range of utility of a medicine, we may fall into error in its use by ignorance of the natural behavior of the disease in which it is exhibited. Before any exact knowledge was possessed of the natural history of diseases, it was simply impossible to be accurate in respect to the influence of medicines over them. Before it was known that a crisis occurs in pneumonia somewhere from the fifth to the eleventh day, endless were the controversies as to the influence of remedies in bringing this crisis about. How valueless became all those discussions, carried on with such earnestness and heat, when the natural history of pneumonia was made out, and it was discovered that medicines had never produced the crisis, which is an entirely natural process. Most important additions have been made to the natural history of diseases within a few years past, and we have now a sure point of departure for the investigations of the future. I affirm this, notwithstanding the pessimistic declaration of Dr. Andrew Clark, made before the medical section of the British Medical Association at their last meeting at Cork. He declares that "of the natural history of most chronic diseases—of their course from first to last; of the modes in which the organism, uninfluenced by drugs, and favored only by the conditions of health, deals with these maladies in their origin, in their modes of progression, in their influence upon other parts, and in their issues either in recovery or in death—we know almost nothing, and certainly not enough for the commonest purposes of therapeutic art." The wholesale iconoclasm of this address is everywhere remarkable, but in nothing has his zeal so outrun his discretion, as in these statements. I need mention but two classes of chronic diseases to demonstrate the error of his statements—the chronic cardiac and renal affections—in regard to which we know their course from first to last, and how the organism, uninfluenced by drugs and favored only by the conditions of health, deals with these maladies in their origin, in their modes of progression, in their influence upon other parts, and in their issue either in recovery or in death.

It may seem a comparatively easy task to determine how far the mind influences the bodily functions in modifying the phenomena of disease, but it is extremely difficult to measure the operations of a force whose nature and source are unknown, and whose powers are exercised capriciously, and without the reign of law. A curious and most interesting book, compiled by Dr. Tuke, has lately been published, in which are brought together more thoroughly than ever before the facts scattered through medical literature, illustrating the influence of mental states on bodily functions. No one can peruse this book without being strongly impressed with the uncertainty which must attend our estimate of the influence of remedies in all of those conditions of disease over which a peculiar mental force may exert a far greater curative power. Everybody has been more or less familiar with the well-attested facts which have existed on this point, but when they are brought together, analyzed, and their lesson comprehended,

we are simply amazed to find that many morbid states, which medicines had failed even to modify, are removed or cured by a force emanating from the mind. If this mysterious force moves, how impossible to form a correct judgment of the share which a medicine or a plan of treatment had in the result.

When Sir Humphry Davy, then a young man unknown to fame, was employed by Dr. Beddoes to make observations with nitrous oxide, among the patients who presented themselves for treatment was a paralytic. Before commencing the inhalation of gas, Davy inserted a thermometer under the patient's tongue to ascertain the influence of the gas on the temperature of the body. The patient was greatly impressed with the mysterious little instrument, and declared, with much enthusiasm, that he felt the influence pervading his entire frame, and was already much relieved. Davy, observing the remarkable influence of hope and expectancy, did nothing more than gravely insert the thermometer day by day with surprising results, for in a short time a complete cure was effected. If Davy had administered the nitrous oxide, the case would have appeared in medical annals as a cure of paralysis by the gas.

When a *religieuse*, in Cincinnati, with prayer and fasting, and after a solemn service in which all of her sisterhood participated, threw herself at the foot of the altar and would not rise until healed—behold! an ulcer of the leg, resisting all other means of treatment—was cured by some drops of water, coming from the far-off, mysterious and sacred spring of Our Lady of Lourdes. In the one case it was a mere impression on the mind without the element of religious faith—a mere dependence on the efficacy of dumb glass; in the other a profound religious sentiment, than which nothing more powerful can sway the human heart—and yet the result is the same.

When we come to analyze the examples of diseases cured by powerful impressions, emotions, faith, hope, expectant attention—whatever the nature of the mysterious force—we find that the cases can be referred to one of two classes: to functional morbid states of the nervous system, or to alterations of structures—organic changes they are called—brought about through the agency of the trophic nervous system. Everybody is familiar with the plentiful examples of the first group, and the second needs no explanation to Philadelphia physicians—for in this city work has been done that has materially advanced the knowledge of the subject. In these two large and important groups of diseases, so much does the cure depend on merely psychical impressions, that it is difficult—often quite impossible—to determine how far the mental state, how far the remedies employed, contributed to the result. The practitioners of that medical jugglery who cure diseases by prayer and the imposition of hands, or by the gifts of the natural healer, understand full well the form of malady suitable for their powers. There is now in the State of Massachusetts, a preacher-doctor who cures by prayer and the imposition of hands—the apostolic method—and therefore denies to his grateful patients the privilege of recompensing him except by voluntary gifts. The penninary outcome of his benevolence is something remarkable, for he has now built up around him on his domain of several hundred acres, a number of stately dwellings for the reception and care of the thousands going to him from all parts of the United States. A patient of mine—a genuine Christian and a woman of the highest excellence, though somewhat credulous and a little superstitious—having heard of the wonderful cures wrought by this Massachusetts apostle, re-

sorted to him. I had from her own lips the story of her experience. She told the great man that she was a firm believer in the efficacy of prayer, having met with many examples, and that she had come all the way from Ohio to be cured of an organic affection of the heart. When the doctor-preacher heard the nature of the malady he made a reply, in which, astonishing as it may seem, she saw no incongruity. He said: "My experience is, that the Lord rarely, if ever, interferes to cure organic disease of the heart." Nevertheless, he expressed a willingness to try, as she had come so far, and, with hands on hers, he did pray fervently, in which she joined as fervently, for half an hour at a time on three days; but my patient experienced no relief, and came home the worse for the moral struggle which she had undergone. My client, as did all who came, it is probable, left a considerable fee in the form of a gift, and was not cured of her delusion, for she heard of numerous miracles that had been wrought there, and she witnessed on all sides the evidences of worldly prosperity; and she may have inspected, for aught I know, the arsenal of crutches, canes, and ear-trumpets which these artists exhibit in proof and confirmation of their powers.

When anæsthesia by the inhalation of ether was demonstrating in the Massachusetts General Hospital, Dr. Eliottson, of London, was engaged in a far more wonderful work, teaching the great lesson, that in a mesmeric sleep surgical operations can be performed without consciousness of pain. So zealously and completely, although in the face of much obloquy, had Eliottson succeeded in convincing sceptical and conservative London of the genuineness of his work, that the discovery of the production of anæsthesia by the inhalation of ether was announced in the *Medical Gazette* under the heading, "Animal Magnetism Superseded." Up to this time the capital operations in surgery were almost daily performed in London whilst the patients were unconscious in the so-called mesmeric sleep. Although Eliottson misinterpreted the phenomena which he observed, and became involved hopelessly in the absurdities and mysticism of Mesmer, he was nevertheless engaged in the demonstration of important truths. If time would allow, I might enter more fully into that remarkable state in which there is a suspension of the methods of consciousness, and show, indeed, that the recent observations of Czermak and others on animals, is an experimental induction of the same state. It seems, indeed, that the condition of the brain in which a peculiar curative influence is exerted over morbid processes, is the opposite of that state in which the activity of the perceptive and volitional centres is in absolute suspension.

Closely allied to this subject are the remarkable phenomena of Burqism, or metallotherapy, which at first excited the ridicule of the scientific, but which seem now likely to contribute to our knowledge of this outlying department of mental and nervous processes. The results obtained by Burq, and especially by Charcot, are such as to merit the close attention of therapeutical investigators, and must, if confirmed, enter into the question of the curative power possessed by certain remedies.

We constantly hear physicians complaining that the published results of others, in respect to the utility of a particular plan of treatment, cannot be realized in their own experiences; that, although Davy cured paralysis by the inhalation of nitrous oxide, they cannot succeed, although they have carefully observed all the conditions of the experiment. They entirely overlook the fundamental fact that one physician

summons to his aid the mysterious mental force in hope, faith, expectant attention; and another represses it, not consciously to himself, by a lack of personal enthusiasm, and still more by a lack of confidence in his own powers and in the power of his remedies—fatal defects in the character of the physician which will not escape the keen scrutiny of the anxious patient. I will not use the vulgar term "personal magnetism," for it has no meaning, and the power is not a magnetic quality or power—not a mysterious gift possessed by the chosen few. That which inspires a supreme, unquestioning, all-pervading belief in the efficacy of the means proposed, is a reflex of the confidence of the physician—not a boastful, self-asserting egotism, not the blind faith of ignorant credulity, but the well-founded convictions of the enlightened therapist, confident in his resources from long experience of their capabilities. "The Lord is on the side of the heaviest battalions," was a favorite saying of the great Napoleon. I hope I shall not be understood to speak in an irreverent spirit. My purpose is to illustrate the lesson, that "God operates, not by partial, but by general laws;" that He gives us the faculties to acquire and to apply knowledge in the treatment of disease; that He does not suspend the laws of nature for our benefit; and that those cures which seem miracles are entirely human and easily explicable.

We derive from the whole subject the important lesson that we have in a peculiar mental state or condition of the great nerve-centres an extraordinary curative power in a large group of diseases, and that in this fact lies one of the greatest sources of fallacy in estimating the value of remedies. Furthermore, it must be obvious that the physiological as well as the empirical method—that both methods are embarrassed by wrong inferences and incorrect interpretations of experience.

The progress of applied therapeutics is equally hindered by the sources of error which I have pointed out. The end to which all our studies are directed as practical physicians is the application of remedial agents to the cure of diseases. An unprejudiced thinker to whom the subject was mentioned would assert with confidence that gentlemen engaged in a pursuit requiring the use of certain agents to accomplish the desired results, would be most solicitous to inform themselves fully in respect to those agents. He would regard it as incredible that a considerable part of our profession are either indifferent or satisfied with vague notions, and that a still larger part fall into routine methods with a few agents which have to do duty for all possible conditions. This widespread inappreciation, indifference, or ignorance of the actions and uses of drugs is due partly to fashion, partly to the unpromising nature of the subject. Within a few years past a therapeutical nihilism has been the position occupied by many of the most influential leaders in modern medical thought. This movement is a result, in part, of the overshadowing importance of physiological and pathological studies. The founding of great laboratories and the brilliancy of discovery in these departments have attracted universal attention to those studies which have become the fashion. We see on every side the efforts put forth to give this direction to medical study and teaching. The desire of the time seems to be to make students, histologists, pathologists, microscopists, rather than sound practitioners, full of the humble but necessary knowledge of the practical departments of our art and science. I hold this to be a perversion of the duty of a medical school. Its first and

highest duty is to instruct students, not to pursue minute researches, but to become thoroughly accomplished physicians and surgeons. No fact is more evident than that the highest order of physicians and surgeons are not men remarkable for their knowledge of microscopy, of experimental physiology, and the other branches of theoretical medical science, and, conversely, that the microscopists and pure physiologists are not remarkable as physicians, and, indeed, cannot be. The attempt to pervert the proper purpose of medical schools, and to give a merely science aspect to medical teaching is a fashion of the time, which, if it gain more adherents, is likely to do serious mischief to the cause of medical education. For young men, allured by the glitter of scientific work, will neglect the important and really more difficult attainments of true professional studies.

It is a mere pseudo-science which is misleading so many that it has become commonplace to know something about drugs and to prescribe them; the new school of pathologists and physiologists look upon the whole business of medicine giving as unscientific, and therefore unworthy the attention of the higher order of medical thinkers. It is a very fascinating doctrine, that to be ignorant of drugs is to be regarded as superior to the commonplace—as being in the higher walks of medical life—and hence many make haste to adopt it, relying for the hereafter on mint-water in the treatment of rheumatism, and similar nihilistic absurdities. The great question of the time is, does it pay? Applying this utilitarian method to the subject, I answer, it does not pay to be ignorant of therapeutics, and I prove my position by some illustrative examples selected from those recently deceased, so as not to be accused of making invidious comparison. The most successful physicians Paris, Vienna, Berlin, London, Edinburgh have had for a generation, were Trousseau, Oppolzer, Traube, Todd, Begbie—all of whom were most careful students of therapeutics, have contributed to our knowledge of the subject, and were diligent prescribers of remedies. These great men were not only successful teachers and clinicians, but had great local renown as practitioners, and each had a large *clientèle*. I beg you will not, therefore, be misled by the depreciation of therapeutics by presumed medical scientists, who are not sufficiently scientific to feel their position assured, but must manifest their superiority by speaking contemptuously of the so-called practical branches. *Sum* is sometimes taken for *habeo*, is an eccentric rule of Latin grammar which is very applicable to the affairs of modern life, and may have been and doubtless was, strongly felt by the old Romans. To have is to be. Applying this rule to the utilitarian side of the question you may be well assured that *to have* a competent knowledge of therapeutics is *to be* a successful practitioner.

Many who have started out on a medical career with a competent knowledge of therapeutics have been disheartened by a failure to obtain the expected results. Failures of this kind arise from two causes: first, from an incorrect appreciation of what nature and art respectively accomplish; and second, from an inability to make a correct therapeutical diagnosis. The rage in our time is to make an accurate diagnosis of disease, and it is an enthusiasm to be encouraged, but there ought to be a corresponding desire to make an accurate therapeutical diagnosis—that is, to ascertain the remedy adapted to the form and character of the disease and the condition of the patient. Into this problem many complex questions enter, and he only can solve it correctly who has an intimate ac-

quaintance with the phenomena of disease, and with the whole range of rational and scientific therapeutics.

What art, what nature can accomplish, is a wide subject which I must merely mention. It is a singular fact that but few young physicians, comparatively, recognize the limits of remedial power. The result is that they may begin with a blind, unquestioning faith, but they end with an unreasoning scepticism.

Having now dwelt on the method and spirit in which therapeutics should be studied, as much as my time will allow, I must next say something of the manner in which it should be taught.

Confronted at the outset of his career with the subjects of materia medica, a student may well stand appalled. A subject which embraces the mineralogy, the chemistry, the botany, the pharmacology of several hundred articles belonging to the three great kingdoms of nature, would seem to require the undivided attention of a life given to the task. The student of medicine cannot become sufficiently well informed in these sciences to utilize them in the study of the materia medica, and at the same time devote sufficient attention to his strictly medical studies. The result is, he abandons an undertaking which seems to him hopeless, cuts the subject of materia medica, and contents himself with the fewest possible facts in therapeutics. He enters into practice with crude notions, and is given to a boundless credulity respecting the curative powers of drugs, or he cultivates a sceptical dilettanteism, or becomes a sceptic, affecting a patronizing forbearance for the weakness of those who have faith in remedies. The condition to which practitioners are now reduced in Paris is gravely stated in a letter which appears in a recent issue of the *Lancet*—so gravely that it can hardly be regarded as satirical: "No wonder therapeutic scepticism is now the rule with prescribers. Thanks to the enterprise of wholesale druggists, a host of *élegant* preparations are always at hand, which relieve the scientific *clinicien* from the ridiculous absurdity of writing a useless formula. Now that diseases are allowed to run their normal course under the watchful eye of the medical naturalist, the exhibition of an inert, but *élegant* granule, must be considered a vast improvement upon the active interference of our physicking forefathers."

No wonder that, at a recent meeting (last month) of the Paris Academy of Medicine, there were loud demands for reform. No wonder that Dr. Andrew Clark, in that recent iconoclastic address from which I have just quoted, cries out that therapeutics, "the highest department of our art, and one of its chief ends, is in a backward and unsatisfactory condition." He attributes this unhappy state of things to several causes; but the first is, that materia medica, not therapeutics, is taught in the schools, and that there is "no physician of experience and authority who teaches the subject of therapeutics."

Where must the reformation begin? Obviously the reformation is demanded in the direction which I have indicated, and which Dr. Clark so vehemently emphasizes.

We must begin by stripping the materia medica of its useless knowledge. We must relegate to the botanist, to the chemist, to the pharmacist, the subject-matters belonging to them, and retain those things having connection with the study and work of the physician. I can best illustrate this by an example selected from the vegetable kingdom: let it be nuxvomica. We have first the names—botanical and chemical. Then follows the source and botanical description, which is Sanscrit to the average student,

and knowledge without any use to the practitioner as such. Next comes the pharmaceutical preparations, and a description of the mode of preparing the tincture and the extracts, and an elaborate account of the separation of the alkaloids—a complexus of chemical and pharmaceutical knowledge of great utility, indispensable, indeed, to the pharmacist, but useless to the physician, who is not engaged in the business of a manufacturing chemist, and who cannot acquire this knowledge unless at the expense of his proper professional education. The best students who make the attempt to master the details of materia medica, acquire but a vague notion of it, and drop the study as soon as possible, except the few who expect to combine the business of pharmacy with the practice of medicine—a union which always results unhappily, and is not to be approved.

Dr. Clark complains in his energetic way that our works in this department consist of materia medica teaching largely, whereas they ought to be devoted to therapeutics only. This is an extreme view to which I must decidedly express my dissent. There is certain knowledge of pharmacy and chemistry which is necessary to accurate prescribing, and which must be taught, if we would use our therapeutical knowledge intelligently. We must know the names of the drug, the forms and preparations in which they are compounded, the active constituents, the doses, the antidotes chemical and physiological, but especially must we have full and accurate information in regard to the effects of the remedies and their uses in the treatment of diseases. All of this knowledge is immediately applicable to the requirements of the physician, and no part of it can be omitted without injury. I hold that the actions and uses of remedies is the point on which the greatest stress should be laid, and no information, empirical or physiological, should be neglected. Let the student have the minutest information from all possible sources of the physiological powers and capabilities of a drug, its behavior as influenced by idiosyncrasy and dose, its applications in the treatment of disease, the fallacies which affect a proper estimate of its powers, the special conditions in which it is useful, why it should be preferred to another remedy of the same class, and in fact any information in regard to it which may facilitate the physician's use of his armamentarium. The artisan is taught the name of the tool, the range of its uses, the mode of handling it under special circumstances; but he is not expected to acquire the mineralogy of iron and the chemistry of steel—subjects concerned with its original construction.

The information which a teacher must convey to a class is derived from two sources: from a study of the authorities who have contributed to the subject; from his personal experiences and reflections. The literature from which he gleans is a wide field and contains a multitude of workers, who differ in capacity, in acquirements, in honesty. The instructor may pursue two methods in imparting his information: he may present in order, chronologically or by subjects, a synopsis of the contribution of each individual worker; he may subject the whole to a careful analysis, weigh the merits and truthfulness of individuals, and present the results in the plainest language. The former plan confuses the student with a multitude of names and opinions that vary and are often contradictory; the latter gives him some salient points on which he may lay hold. I maintain that the latter plan is the true one—that it is the duty of the instructor to analyze the complexus of facts and opinions—to guide the intelligence of the student through a

maze to right conclusions. Those who wish to engage in investigations on their account are either advanced students or graduates, who possess the knowledge necessary to find their way through the labyrinth.

I hold, further, that the instruction should be, as far as possible, objective or demonstrative. The lecturer may content himself with stating that drugs will produce certain results—that strychnia will cause tetanic spasms, and that conia will paralyze—and he may illustrate the action of strychnia by an exposition of some famous medico-legal case, as the poisoning of Cook by Palmer, and the action of conia by recounting from the Phædro of Plato the death of Socrates; or he may at the moment demonstrate the effects of the drug by an experiment which makes the fact memorable in the student's mental experiences. The chemist who merely tells his students that water is composed of oxygen and hydrogen, and does not demonstrate it by experiment, will hardly have done his duty. The experiment vivifies the bald fact, and the impression made is permanent. But how demonstrate your therapeutical facts? This brings me face to face with the great vivisection question. Though an advocate for rightly conducted vivisections, I protest against cruelty to animals, who are God's creatures. I protest against those barbaric sports in which more animals suffer yearly—hunted to death—than have in all time been under the knife of the vivisector. More than all, I protest against that inhumanity to man—the outcome of an unreflecting sentimentality—which prevents those scientific investigations having for their end incalculable benefits to man. Some of our most important remedies and physiological knowledge of the highest importance have been, and only could have been, obtained by experiments on animals. If animals are sacrificed for the support of men's bodies, why should they not contribute to the improvement of men's minds? Your sentimental philosopher does not reflect on the humanity of the butcher, except for the toughness of his matutinal steak. Not to occupy further time with well-known arguments in favor of vivisection, I hold that the actions of drugs should be illustrated as far as practicable by experiments on animals, but the experiments must be decorous, not revolting, not cruel, and made strictly to advance or to impart knowledge for the benefit of our fellow-man. In these experiments animals have small occasion to suffer, for the medicament or the anæsthetic so far obtund the sensibility of the centres of conscious impressions that pain is not felt.

Why torture dumb brutes by experiments, which after all cannot be utilized in the treatment of men's diseases; for has it not been shown that the actions on men and animals differ—that rabbits eat belladonna with impunity, and pigeons cannot be affected by opium? I might explain to you how idiosyncrasies exist in men and animals alike, and are usually more apparent than real; but let me answer your objections by a quotation from the most competent authority of modern times—Claude Bernard. He declares in that remarkable work—"Introduction to Experimental Medicine" (p. 218)—that "experiments on animals with deleterious and noxious substances are very useful, and perfectly conclusive for the hygiene and toxicology of man. The researches on medicaments or poisons are equally applicable to man from the therapeutical point of view, for the effects of these substances are the same in animals as in man, except the difference in degree." This opinion, based on the largest experience, and after a career of brilliant dis-

covery, might be illustrated and enforced, if I had the time, by the examples of benefits to the race obtained in this way.

The crusade against vivisection in England, which has attained extraordinary volume and force within a few years past, is an outgrowth of dog-worship, which has now become a form of religion in the upper classes of society. With hair perfumed, powdered, and curled, his canine worship sits at table with his mistress, rides in the park in the afternoon, sleeps on downy pillows at night; he has his maid to anticipate his wants, besides the undivided attention of his mistress, and when ill he is waited upon by a celebrated physician. He makes no return to society for the protection and benefits he receives; he pays no taxes; he merely barks and growls in return for the love of his mistress, and is altogether an ungrateful dog; but he has driven physiological research out of England, and the gentlemen who were engaged in an important series of investigations on the biliary secretion were compelled by him to go over to France. An epidemic of hydrophobia and the loss of several titled ladies will be necessary to prevent the apotheosis of the dog, and to put vivisection in its proper position—for a cure for hydrophobia can only be arrived at by experiments on this at present distinguished member of society.

Original Communications.

CASE OF COMPOUND DISLOCATION OF THE ANKLE-JOINT, WITH FRACTURE—RECOVERY.

By B. A. CLEMENTS, M.D.,

SURGEON AND BREVET LIEUT.-COLONEL U. S. ARMY.

THE best treatment of compound dislocations of the long bones, and particularly of the ankle-joint, would seem to be still not definitely determined, wide differences of opinion existing among eminent teachers up to the present time.

Professor Frank H. Hamilton, after discussing the subject with even more than his usual ability and discrimination, determines generally in favor of resection as compared with other modes of procedure, and attaches great value to the rest and relaxation of the muscles thus secured, as well as to the greater resulting mobility of the joint, remarking that "after resection I have thus far heard of no cases in which complete ankylosis resulted;" and he writes of the "great hazards" attending attempts to effect a cure by reduction without resection.

Mr. T. Holmes (System of Surgery, vol. i., p. 825), on the contrary, in stating the "general considerations" applicable to the treatment of these injuries, says, "that in joints of the lower extremity no bone should be removed unless absolutely necessary, and every attempt made, by enforcing strict rest and confined position, to induce ankylosis."

Billroth, in the fourth edition of his Surgical Pathology, remarks in regard to reduction alone, that "we may sometimes hope for a cure by suppuration, with a subsequent stiff joint; but, as experience shows, it is always a dangerous experiment," and he highly commends resection as compared with amputation, if the injury of the soft parts be not great; whilst in his more recent eighth edition he says, "less attempt is made than formerly to obtain movable false joints after resection, but more frequently we seek by partial

removal of the bones . . . to secure ankylosis of the joint."

Accepting these views as expressive of the current practice, it is thus seen that these eminent authorities are not wholly agreed as to the necessity of resection, nor as to the greater desirability of motion or ankylosis in the injured joint; and whilst it may not be possible to establish such general rules as shall be applicable to every particular case, it may be assumed that the question can be narrowed to the case of particular joints, and greater definiteness and certainty in treatment secured only by carefully recording in detail the results of clinical experience.

With this view I give the history of the following case, which was under my care, as an interesting contribution to the clinical history of compound dislocation of the ankle-joint:

Musician Adolf Bill, 14th U. S. Infantry, age 24, was caught under a falling bank of gravel and stones on October 11, 1878, near Fort Douglas, Utah. He was standing at the moment of the accident, and was almost entirely covered by the earth; his companions very speedily unearthed him, and I saw him within a half hour afterwards. His right foot was lying at right angles to his leg, and on removing him to the hospital it was found that, in addition to the injury of the ankle, he had an extensive lacerated wound of the scalp, with much extravasation of blood under the scalp, near the wound; the skull was bared but not fractured; blood ran from his nostrils and mouth, his forehead, face, and chest were much contused and swollen, and he was nearly insensible. His right knee was much swollen and contused, as well as the tissues over the upper half of the right tibia, though he complained more of pain in the left lumbar region, against which, it was learned, the handle of a spade he was using had been driven. The wound in the scalp was at once closed by silver sutures, and required no further care at any time. The accident occurred at 10 A.M., and he suffered the usual symptoms of shock for three hours and a half, but by three o'clock reaction had occurred, his skin became warm, and his pulse rose to 130°, and ether being administered, I proceeded, with the kind assistance of Dr. I. F. Hamilton, of Salt Lake City, to make careful examination of the injury to the ankle-joint.

The foot was completely turned up along the inner side of the leg, lying on its side, and the tibia and fibula both protruded outwards through a straight opening in the skin over the upper part of the outer malleolus; both bones were completely denuded, for the space of three inches, of all tissue save periosteum and some connective tissue, almost as neatly as if cleanly dissected; the fibula was not broken at the usual point above its malleolus, but the extremity of the latter was broken off, leaving a rough surface, and the tip of the inner malleolus and the anterior edges of the articulating surface of the tibia were crushed and ground off as if the bones had been driven and twisted into the gravel with great force, leaving all the rest of the articular cartilage intact. There were no fissures or other fracture of the bones of the joint, nor were there any signs of torn tendons, and the tibial arteries were intact and the foot warm.

I removed the roughened surfaces of the malleoli and anterior edges of the articulating surface of the tibia with bone forceps, and after cleansing the parts thoroughly with carbolic acid in solution (1 to 40), firm extension was made by Dr. Hamilton, and the bones restored to position through the wound in the skin over the site of the upper part of the outer malleolus, it being necessary in order to effect the return

of the bones through the constricting edges of the skin wound, to insert a spatula under the latter and forcibly raise and stretch them. It was then seen that this wound had plainly not been made from without, but evidently by the bones from within, there being no marks of contusion on the surface, and the edges being lacerated in slight degree, presenting the appearance of thick wet paper when it is torn: it was two and a half inches in length, and from behind forward in direction. The wound was again thoroughly syringed out with carbolic solution (1 to 40), and the edges, except at the lower angle, brought together with silver sutures. A long India-rubber drainage-tube was inserted into the joint through the lower angle, and its outer end into a bottle containing carbolic solution.

The wound was dressed by Lister's method, every detail of which was observed, except that the "protective" silk and the few instruments used were not dipped in carbolic solution. The limb was laid on a splint with a foot-rest. Morphia was given, and at 9 P.M. his pulse was 120, and temperature 98.7°.

It may be well to again observe here that but a small portion of the articular cartilage was removed, and that practically the removal of bone scarcely amounted to a resection.

The next morning, October 12th, his pulse was 104, temperature 100.9; he had slept at intervals during the night. Three measured ounces of bloody serum had been discharged into the bottle through the long drainage-tube. In the afternoon his pulse had risen to 130, he was very restless and semi-delirious, and the discharge from the tube had nearly ceased. At 8 P.M. carbolic solution was injected through the tube, and much bloody discharge forced into the dressings, which were then removed, as well as the tube itself, which was found to be perfectly pervious. The wound being further syringed out with carbolized water, the tube was reinserted with difficulty, the open angle of the original wound being nearly two inches above the cavity of the joint, and Lister's dressing was applied in every detail, it being necessary to give chloroform during the time.

Oct. 13th.—The temperature this morning had risen to 103.6, and his pulse to 120; his tongue was dry, and he was very restless and talkative. There was no discharge from the tube, and it was seen that it had not been properly reinserted last night, and it was therefore wholly removed. By 8 P.M. his pulse fell to 100, and his temperature to 101.8. His bowels moved with relief to him, and his urine was drawn off by a catheter. The knee of the injured leg was hot, much swollen, and sensitive.

The following morning, October 14th, his pulse was 104, temperature, 103°. The dressings were saturated with bloody, dirty serum, which did not, however, smell badly; they were removed, and the joint found tumefied with dirty serum. It was thoroughly syringed out, the tube now reinserted accurately, and the anti-septic dressing renewed—all under chloroform.

The knee was still more swollen and tender, as well as the upper part of the leg. The speedy good effects of cleaning out the joint were manifested in the evening by his pulse falling to 100, and temperature to 100.8°. Up to 8 P.M. there had been 5 ij. of bloody serum discharged into the bottle through the tube. His tongue lost its dryness, and he slept fairly this night.

Oct. 15th.—Pulse, 100; temperature, 100.8°. No soiling of dressings, and no odor; the tube discharged into the bottle readily an ounce of reddish serum, and continued to do so without obstruction,

there being an additional ounce and a half in the vial at 8 P.M. The catheter was constantly necessary.

Oct. 16th.—At four o'clock this morning he became very restless, though at 8 A.M. his pulse was but 96. Temperature, 100.1°. $\frac{3}{4}$ i. of flaky serum had been discharged into the vial, it was for the first time untinged with blood. But by 10 A.M. he became delirious, and his temperature had risen to 103°. Fearing that the tube did not discharge all the fluid contents of the joint, I removed the dressing and found the joint full, but not distended, with thin ill-looking pus. Under chloroform the joint was thoroughly injected and cleansed out, the tube reinserted, and the Lister's dressings removed. Whiskey was given in milk; he continued mildly delirious, but by 9 P.M. his temperature had fallen half a degree, and the tube had discharged three drachms more of bloody pus. He slept pretty well under the use of whiskey and morphia during this night, and on the next day, Oct. 17th, his pulse at 8 A.M. was 100; temperature, 102°. A half ounce of thin pus had been discharged through the tube, and he was rational. Owing to the curved direction assumed by the tube in passing it into the joint through the original wound, it was evident that it could not freely discharge the pus now forming, and I consequently removed it and made a free incision into the joint some two inches lower down, releasing a spoonful of pure pus, and through it inserted well into the joint a drainage-tube made of an elastic catheter. His temperature fell a half degree by 9 P.M., and there was no evidence of discharge.

Oct. 18th.—Pulse, 104; temperature, 100.8°. Dressings were much soiled, and were renewed.

The following day, Oct. 19th, there was less discharge from the joint, but the knee and upper part of the leg were much swollen. On the 20th there was fluctuation along the tibia, and a free incision was made some four inches above the ankle, giving exit to $\frac{3}{4}$ iv. of normal pus.

Both by probing and injection it was determined that there was no communication between this suppurating surface just incised and the joint.

The following morning, Oct. 21st, the pulse had fallen to 84, and the temperature to 99.6°. The discharge of pus from the incision made yesterday was normal in appearance and quantity, and that from the joint more moderate; and though the temperature rose to 102.2° in the evening, the pulse was but 88. I applied a Smith's anterior wire splint to the leg, which gave him great comfort and enabled the dressings to be easily applied.

The foregoing details of this critical period of the case illustrate the now oft-told story of the necessity of securing a free discharge from wounded joints and the great and serious disturbance arising from even a few hours' retention of the fluids, and I will condense as far as may be possible the rest of the history.

He had early been put upon nutritious fluid diet; attention was given to securing a movement of the bowels, as much tympanites existed; he still complained most of pain in the lumbar region where the spade-handle had been forced against him, and it was necessary to use the catheter three to five times in the twenty-four hours.

On Oct. 22d the discharge from the joint was clear, yellow and gelatinous, and about $\frac{3}{4}$ i. in quantity in the twenty-four hours.

On Oct. 25th, in the evening, he had a spasm of the muscles of the face and arms, preceded by chilliness

and attended by faintness and feeble, rapid pulse, which passed away within an hour or so under the use of stimulants. He had another attack of this kind on the evening of the next day. The thumbs were turned in on the palms and pupils dilated, and he was unconscious. This was also preceded by chilliness, and the pulse soon rose to 120, and temperature to 103°. For this I gave a few drops of chloroform internally and an enema of oil and turpentine, and his bowels soon after freely moved, with great and speedy relief to all the symptoms. The high temperature was evanescent, having fallen almost to 100° by next morning, and an examination showed the wounds in proper condition, the discharge being only about two drachms a day, and thin and sticky. This spasm recurred on the evening of the 28th, and I gave a few drops of chloroform by inhalation, under which he soon regained consciousness. I concluded that these attacks were due to reflex irritation from the stomach, as he now ate very heartily, and greater care was taken in limiting the amount of his food.

On Oct. 30th he had a slight chill which was not followed by any unusual elevation of temperature, and again at noon on Nov. 2d, which raised the temperature to 104° at 2 P.M., and which were precursors of inflammation external to the joint; for, on the 5th, the inner side of the foot was red and swollen, which greatly increased, so that by the morning of Nov. 7th the foot was tense, red, and œdematous in every direction, whilst the discharge through the tube from the joint had almost entirely ceased, and the surfaces heretofore drained by it appeared to be nearly healed. It seemed clear that the inflammation was confined to the exterior of the joint. Under chloroform, I made this morning a deep incision on the inner side of the joint down to the bone itself and another on the outer side near the original wound, which had nearly healed, but no pus was discharged from either incision. In the afternoon the temperature rose to 102°, and fell one degree by 8 P.M., with pulse at 96. The following day the foot was still more swollen, there was no suppuration from any of the incisions, the temperature varied from 99° in the morning of this day to 102° on the evening of the 10th; but there was no escape of pus until the evening of the 12th, when reddish pus was discharged through the opening made over the tibia on October 20th.

On Nov. 14th a deep incision two inches in length was made down to the bone on the inner side of the foot, and free communication established with the incision over the tibia, discharging some $\frac{3}{4}$ ij. of ill-conditioned pus. A long probe, passed through the tube entirely across and through the joint, failed to communicate with the new incision; but when passed through the original wound and behind the tendo-Achillis it entered the suppurating surface on the inner side. It was conclusive that all this pus and inflammation was external to the joint, whose surfaces seemed apparently healed by granulation. The next day the swelling was greatly diminished, and by the 16th the discharge of pus was small, and the patient in much ease and good spirits. By the 20th of November the discharge had diminished to one drachm per day on the inner side, and a few drops of clear, gelatinous fluid issued from the tube. On the 21st the tube was removed and a small piece inserted just within the outer edge of its site to prevent too rapid closure. At this time there was a marked difference between the pulse at 6 A.M. and at 8 A.M., it being accelerated as much as twenty beats immediately after eating his breakfast. This state of the pulse existed until the 14th of the next month, and seemed to produce no

inconvenience and to be due to no cause directly dependent on the condition of the joint.

On the 24th the foot swelled on the outer side and a few drops of pus issued from the site of the tube, which I in consequence reinserted; and on the following day an ounce of pus was discharged from the original wound. The tube was removed finally on the 28th, and the opening firmly closed at once. The same condition arose just above the instep on the 29th and on the inner side of foot on Dec. 2d, and a very slight discharge of pus, not more than two drachms occurred on the 4th, through the openings already made, with speedy relief to the tenderness and swelling.

By Dec. 6th the appearance of the foot was much improved, all the openings being closed by granulation except that over the tibia, though it continued oedematous; and a flannel bandage was tightly applied to the foot, leaving the opening in lower third of the tibia free, as there was a discharge of reddish pus from it which appeared to come from below.

This discharge had nearly ceased by the 13th, and the pulse and temperature had been for some days nearly normal, but on the 19th a general swelling and shiny appearance arose over the whole foot, and on the 20th caused much pain, the pulse at 5 P.M. of this day rising to 116, with a temperature of 100.6. The foot and ankle were swathed in lint wet with hot water, and covered with oiled silk, which was continued until the 23d, when half a drachm of pus was discharged from the inner side, with relief and diminution of the glazed and red appearance. A few drops of pus continued to be discharged daily. On the 24th and 25th of Dec. the pulse rose to 100 and 104 respectively in the evening, and the temperature to 101° and 102°, due, it was thought, to some excess in diet. On the evenings of Jan. 2d and 3d the pulse and temperature again rose, and speedily fell to nearly the normal on the discharge of but a few drops of pus, which appeared not to be deep-seated. This was the last disturbance from this cause and the details are given to show the great irritability of his system, and the disturbing effects of even a few drops of imprisoned pus.

On Jan. 5, 1879, the Smith's anterior splint, which had given him such freedom from pains and myself such convenience in the frequent dressings, was removed, and a course of frictions, shampooing, and the use of compressing flannel bandages adopted, under which the swelling and congestion of the foot and ankle rapidly and regularly diminished, so that he was on crutches in a few days and could walk with only the aid of a cane by about Feb. 1st.

He was discharged from the hospital on March 2d, 1879, and at that time the condition of the foot was as follows: The soft tissues of the foot and ankle were almost normal in appearance; there was firm ankylosis of the ankle-joint, and its circumference was only one-eighth of an inch greater than that of its uninjured fellow. The foot preserved its natural relation to the tibia; its lateral motions were preserved as well as the movements and functions of the toes. He suffered no pain, and before his discharge from the service on April 1, 1879, he had frequently walked with only the aid of a cane to and from the city of Salt Lake, a distance of three miles, over a rough and hilly road, without great fatigue or injury to his foot.

Although a successful result was attained in this case, it was at the expense of great risk and suffering to the patient, and of greater care and attention on the part of the surgeon and attendants than I have known

necessary in a surgical experience of over twenty-five years. Notwithstanding his youth and natural vigor, his condition was certainly precarious for several weeks, and I think it will be admitted that the effort to save the foot without essential resection was certainly, as Billroth regards such attempts, "a dangerous experiment."

I am confident that it would have been better to have removed cleanly the articulating surfaces of the tibia and a thin slice of both bones, and in this sustain the opinion that resection in such cases should be preferred to other modes of treatment; and I incline to believe that both patient and surgeon may well be satisfied to secure ankylosis without seeking to obtain motion in the new false joint, and thus entail the additional risk of constitutional disturbance and perhaps of an insecure joint.

I invite attention to the use of the long drainage-tube—one end being inserted into a bottle containing a disinfecting fluid, as first practised by Mr. McGill, of Leeds, England; to the fact that the peri-articular suppuration did not depend on perforations of pus from the cavity of the joint; and to the rarity of the occurrence of this dislocation without fracture of the fibula above the malleolus.

FORT DOUGLAS, UTAH, July 1, 1879.

ASTHMA FROM REFLEX CAUSES.

By WM. PORTER, A.M., M.D.,

ST. LOUIS, MO.

AMONG many causes of bronchial asthma, reflex irritation seems to play an important rôle. In not a few cases the phenomena attending the disease cannot be explained by any theory of local lesion within the lower respiratory tract—the cause is from without. The following case affirms this:

A merchant, æt. 40, asked advice on account of obstruction in the superior pharynx. For several years he had had asthma more or less constantly, and had exhausted all the ordinary measures for relief. The inhalation of compressed air had also been administered by a most experienced physician. The paroxysms gradually became more violent as the pharyngeal condition progressed. On examination of the chest only slight emphysema was found, and an occasional coarse mucous rûle heard, equally on both sides. In the pharynx the whole of the vault was filled with a gelatinous mass—small polypi closely crowded together. A probe was introduced, and, so soon as this mass was touched, the patient had severe dyspnoea, lasting several minutes. Removal of the polypi was of course advised with the hope that subsequently the asthma might be relieved by proper treatment. As soon, however, as part of the polypi was removed—which was done with difficulty, owing to the recurrence of the paroxysms of dyspnoea—a diminution of the bronchial symptoms was evident. A few days after the last polypus was removed the patient was free from asthma. Two months later there was a slight return of the old trouble. Several small polypi, which had recently formed, were removed, and the pedicle of each touched with chromic acid. Since then, eight months, this patient has been free from asthma.

It will be noticed in this case that the bronchial irritation progressed *pari passu* with the growth of the polypi; that removal of the polypi relieved the asthma, which recovered when new polypi formed, and disappeared entirely when the neoplasm was

finally destroyed. It was not thought, in the first instance, that the asthma was wholly due to the presence of the polypi, as now seems evident. The impression made upon the nerves of the pharyngeal plexus was doubtless transmitted directly to the pneumogastric through the ganglion of the trunk. It has been proven that respiration may be impeded through irritation of the pneumogastric nerves, causing approximation of the cartilaginous rings of the bronchi (Bert and Traube), and in this instance the source of the irritation was in the pharynx.

Another case, in some respects similar: A gentleman, *æt.* 37, who suffered from severe attacks of bronchial asthma for at least a year, was found to have a greatly enlarged and painful tonsil. He also complained of pain, more or less constant, in the region of the trapezius muscle. Remembering the above case, as well as acting from general principles, I advised and effected removal of the diseased tonsil, where, deeply imbedded in the portion excised, was discovered a hard calculus, one centimetre in its greatest diameter, and very rough. The patient had several slight paroxysms of asthma during the healing of the pharyngeal wound, but since then—three months—has had no return. The pain in the shoulder has also disappeared. Referring again to the nerve-distribution, we find the tonsillar branch of the glosso-pharyngeal nerve directly connected with the pharyngeal plexus, through which, as stated, the pneumogastric may be influenced. The pain in the trapezius muscle was probably due to irritation of the spinal accessory nerve. This, by the way, is not infrequent in cases of chronic pharyngitis.

Disturbance of the pneumogastric, producing asthma, from causes located elsewhere than in the pharynx, may occur. Ovarian disease is often the source not only of apparent asthma, but of cardiac irregularity, while uterine complications are responsible for these symptoms—for here they are but symptoms—in many instances.

A case in point: A lady, *æt.* 46, was seen in consultation on account of rapid heart action and severe attacks of asthma. The physician in charge, after repeated and patient effort, had found no evidence of organic lesion except a well-defined local tenderness over the left ovary. Our joint examination confirmed this; the lungs were certainly free from disease, and, except that the area of cardiac dulness was somewhat enlarged, the heart seemed normal. Respiration, 24; pulse, 120; temperature, 99.6° F. The menstrual function was imperfect, but had not entirely ceased, though the patient was seemingly near the menopause. In the absence of evidence of pulmonary or cardiac disease, the treatment was addressed to the ovarian irritation, for it was presumed that this, by reflex influence, produced both the dyspnoea and rapid heart action, the latter in turn causing the slight cardiac hypertrophy. This opinion was justified by the result. Counter-irritation was made over the ovarian region, and perfect rest enjoyed. No other treatment, except small doses of potassium bromide, was used. In a week the pulse had fallen to 100, and the attacks of dyspnoea were less, both in frequency and severity. After a month there was little, if any, reflex disturbance.

Schultz (*Allg. Zeit.*, 1876) and Weber believe that bronchial asthma is due to vaso-motor neurosis, while Bruner (*Sovrem. Med.*, Warsaw, 1877), working in the same direction, declares that "asthma bronchiale is dependent upon an over-stimulation (exhaustion?) of the pneumogastric nerve." This author, in accordance with his belief, seeks to cure asthma by applying

the galvanic current to the affected nerve, and with some success. Some cases there are, however, as those we have mentioned, in which there is a definite cause for the reflex stimulation. Hence we conclude that in all cases of asthma it is important to determine whether reflex influence is present, and, if so, to remove the remote cause of irritation, if possible. Where this is the prime factor it is not likely that any of the ordinary methods of treatment alone will suffice.

There are many instances, doubtless, where structural lesions of the bronchial mucous membrane follow impressions made upon the pneumogastric nerve. The vaso-motor supply may be thus so influenced that effusion and secretion result. Where such conditions have followed reflex disturbance, removal of the primary cause cannot always effect immediate relief. It is, however, a *sine quâ non*, and equilibrium of the circulation in the mucous membrane of the bronchial tubes is generally soon restored.

Progress of Medical Science.

POISONING FROM THE USE OF DUBOISIN DROPS.—*The Lancet*, for September 6th, reports eight cases occurring at the ophthalmic department of St. Thomas's Hospital, in which toxic symptoms were produced by the use of duboisin drops. The preparation employed was a four-grain solution of the sulphate of duboisin; two or three drops were used, and in some of the cases repeated a few times. The drug was given to assist, or as a substitute for, atropia. The prominent symptoms produced were dizziness, delirium, and inability to walk. In only a few cases was there dryness of the throat. The symptoms subsided in a few hours or a day. The cases seem to show that the drug is more powerful than atropia, and has a somewhat different constitutional effect.

BLOOD-POISONING AND ANTISEPTIC SURGERY.—Mr. Wm. S. Savory, surgeon to St. Bartholomew's Hospital, discussed the above subject before the British Medical Association at its last meeting, taking ground against the Lister method. Blood-poisoning he defined to be the introduction into the blood of matter capable of producing putrefaction. He considered it well established that this septic matter is an organic particle, either animal or vegetable.

The system is in danger from it:

1. If it be in contact with the wound.
2. If the wound have not a healthy surface. The two great objects, therefore, in surgical operations, are to exclude all putrefying or decomposing fluids from the wound, and to keep the wound itself in the healthiest state possible, it being demonstrated that septic poison cannot pass through healthy granulations. If these two things are done, there can be no danger from blood-poisoning.

According to Mr. Savory, Mr. Lister's method aims at only one of these objects—that of the rigid exclusion and prevention of foul fluids. This aim, though theoretically good, practically is not always attained.

Besides this general objection, the following other points against Lister were made:

1. There are no statistics showing better results from Lister's than from other methods; in fact, none that are quite so good.
2. The fact that wounds often heal by first intention, or with great rapidity, when exposed to the air,

throws doubt upon the theory of the antiseptic method.

3. Mr. Savory's personal experience and observation had led him to believe that, as a rule, wounds heal more directly and quickly under simpler plans.

4. He denied that under Lister's plan operations can be performed which would not be attempted under ordinary methods.

5. Blood-poisoning does occur under the Lister plan, even in the best hands. Thus, instead of excluding septic fluids from the wound, it may imprison them there.

6. The dressing is very often irritating.

7. The fact that the dressing generally prevents the formation of pus, is of little weight. Healthy pus upon a granulating wound is a favorable sign.

8. The drainage tubes are very often a source of local and general irritation.

The principle of the Lister method is sound but narrow; and the practice has not yet shown as good results as those from other methods.

RESUSCITATION OF DROWNED PERSONS.—A new method for the resuscitation of the drowned is described by Dr. Thos. E. Satterthwaite. It is claimed to be simpler than any of the already recognized methods; it needs but one operator; but little muscular force is called for, and the person is subjected to no rough usage. The directions are as follows: First, try and get something warm and dry to exchange for the wet clothing. Second, try and clear the air-passages of water by slightly elevating the body, while the mouth is wedged open and the tongue depressed. In half a minute or less the water will be driven out.

Third, turn the person over on the back, with the head still a little lower than the body, keeping the mouth wedged open with a bit of wood, and the tongue depressed with the finger of one hand. Then, sitting beside the person, make upward pressure with the other hand upon the bowels. Press slowly at first, then remove the hand that the air may enter the lungs. Repeat this three or four times a minute in the beginning, then increase to fifteen or eighteen times a minute.

If there is an assistant, the arms may be grasped and Sylvester's plan used in addition. Ammonia or smelling-salts may occasionally be applied to the nostrils, to stimulate the nerve-centres.—*Public Health*, July 5, 1879.

A CASE OF UNILATERAL PARALYSIS AGITANS.—Dr. Dyce Duckworth, assistant physician to St. Bartholomew's Hospital, reports the following interesting case of unilateral paralysis: The patient was a herdsman, aged sixty, well-nourished, and with no history of syphilis or intemperance. Two years previously, having been exposed to wet, he was taken with pains in the right arm; tremblings gradually supervened in the right hand; these extended up the arm, and at length obliged him to leave his work.

When presented for treatment, these tremblings had grown still worse; they diminished on movement of the arm, but began again when anything was grasped. They ceased during sleep. The flexor muscles were somewhat contracted, the power of the arm weakened; sensation was unimpaired. There was much restlessness at night, and the patient was awakened two or three times with paroxysms of pain and trembling in the arm. There was no tremor in the head, and the speech was unaffected.

The patient was placed on the bromide of camphor, it being gradually increased from one to fifteen grains

a day. Subsequently, the galvanic current, twenty six cells, was given daily. He gradually improved, so that he was able to pick up things and even write. The case then remained stationary, and was finally discharged.

The case illustrates a rather unusual form of the onset of the disease; it shows also that the bromide of camphor, recommended by Charcot, is of considerable value as a palliative.—*The Lancet*, Sept. 6, 1879.

THE OPEN METHOD VERSUS LISTER.—To illustrate the success which may attend the treatment of surgical cases on ordinary surgical principles, the following statistics were given by Mr. Savory in his attack on the Lister dressing. At St. Bartholomew's Hospital, in 1876, the number of deaths from pyæmia, after operations, was 2, or .49 per cent. In 1877 the deaths from the same cause were 4, or .95 per cent. In 1878 the deaths were 4, or .96 per cent. During the three years there was a total of 18 deaths from blood-poisoning after 1,235 operations, this being at the rate of 1.44 per cent.

PARACENTESIS PERICARDII A JUSTIFIABLE OPERATION.—The above operation, which after trial has been pretty generally abandoned in New York hospitals, is urgently recommended by Dr. John B. Roberts, of Philadelphia. The operation was proposed two hundred years ago, but only seven recorded cases of the operation could be found in America. Dr. Roberts, however, collected elsewhere in all forty-nine cases, of which twenty-three recovered.

The cases requiring paracentesis especially are those where a sudden effusion occurs in acute articular rheumatism. In Bright's disease, pleuro-pneumonia, and purulent pericarditis, not so good results can be expected. The operation should be done with an aspirator; the best point for the needle or trocar being the fifth intercostal space, one and a half inches from the middle line (not the left edge) of the sternum. If the fluid reaccumulates the tapping should be repeated, and if it becomes purulent a drainage-tube may be left in the wound.—*Phila. Med. Times*.

OBSERVATIONS IN ONE HUNDRED CASES OF CARCINOMA.—Some very interesting facts in regard to carcinoma, as it occurs in this country, have been collected by Dr. T. E. Satterthwaite and Dr. W. H. Porter, and presented in the form of an elaborate monograph in the *New York Medical Journal* for September. The histories of the cases have been followed up with great care, ninety-five per cent. of the cancers having been examined microscopically. There is no previous set of cases that has been studied so thoroughly and minutely.

The authors classify the carcinomata into five groups, viz.: 1. Epithelioma; 2. Scirrhous; 3. Encephaloid; 4. Colloid; 5. Cauliflower growths. This division and the descriptions given of each are much like those ordinarily accepted. Under the head of epithelioma is included rodent ulcer, and the differential diagnosis between it and lupus vulgaris is given. Rodent ulcer is considered a growing inward of the rete, which does not, however, extend as rapidly or as deeply as the ordinary epithelioma, and rarely forms the epithelial cylinders characteristic of that affection. Rodent ulcer is in fact only a low or mild form of epithelioma. The cases of each form of cancer are analyzed, and presented in tabular form, showing the age, sex, condition, occupation, date of beginning of growth, its locality, cause, the family history, enlargement of lymphatic glands, treatment

previous to operation, date of operation, condition of health previous to cancer, whether pain was relieved by the operation, whether the growth was more rapid when it recurred, date of recurrence, interval between period when first noticed and first removed, number of recurrences, number of operations, extent of operations, interval between first removal and death, duration of non-fatal cases, length of the course of the disease, date and cause of death, locality of recurrent growth, complicating diseases, variety of the disease, name of the examiner.

Under nearly all of these heads some more or less positive conclusions were deduced; and the results are compared with those of Paget, Winiwarter, and other observers. Some of the more important ones may be noted.

In regard to scirrhus cancer the disease was found to commence between the ages of forty-two and forty-six, the least age being twenty-eight, the most advanced seventy-six. External scirrhus occurs more frequently in females; internal, in males. 80 per cent. of the cases occurred in the breast, and next in frequency were the stomach, the liver, and the uterus. In 36 per cent. some form of traumatism, such as blows, abscesses, or ulcers, was assigned as the cause, this being a much larger per cent. than is usually given. About 30 per cent. had a family history of carcinoma. Such treatment as has been received previous to operation had resulted in no good; this treatment consisting of arsenic, electrolysis, etc.

The previous health had been good in 82 per cent., and it was inferred that scirrhus cancer was a disease of established health. The operation for removal caused relief from pain in 63.41 per cent. of the cases, a showing favorable to operative procedure.

On the whole, the rate of growth after removal and upon recurrence appeared to be more rapid than before, though this conclusion could not be made positively, and is at variance with that of Paget.

The average period between inception of the disease and operation was seventeen months, the average interval between first removal and death, twenty months. This does not include the non-fatal cases, which would bring up the average to over twenty-five months. The person who had lived longest was operated on four times, and the fact is emphasized that where the greatest number of operations have been performed, there is the greatest duration of life.

In regard to the reliability of the microscope in making diagnosis of these growths, it is stated that in not one case, where a good specimen was furnished, was a mistake made in assigning them to their proper class.

It is further stated that scirrhus never undergoes any change when it returns to the same site.

No positive relation of the disease to phthisis or syphilis could be made out.

Scirrhus cancer embraced forty-one of the one hundred cases. Epithelioma came next in frequency.

This occurred at an average age of fifty-four years; three-quarters of the cases being males. One-third of the cases were located on the lip. In 32 per cent. smoking a pipe was assigned as a cause, and in over half the cases there was some kind of traumatic cause given. In 13 per cent. there was a family history of cancer.

The treatment previous to operation had, in most cases, been the application of a saturated solution of terchloride of antimony, and this had often done much good. In three-fourths of the cases the general health had been good. The rate of growth after

removal was, in 44 per cent., more rapid. In 70 per cent. of the cases it had not returned.

The average duration of all the cases was over forty-four months, some of the cases being still alive. An important deduction was made on the microscopical examinations. In no case was a sarcoma seen to undergo conversion into a carcinoma, or be in any way associated with it. The converse was also true.

Some important clinical facts are also given in regard to the variety and site of carcinoma. Given cancer of the breast, and it will almost certainly be scirrhus; given cancer of the eyelid, and it will almost certainly be rodent ulcer; given cancer of the liver, and it will almost certainly be encephaloid.

THE HYPOPHOSPHITES IN PHTHISIS.—The question of the value of the hypophosphites in phthisis has been revived, with varying testimony in regard to them. A writer in a California journal praises them, to the disparagement of cod-liver oil. Dr. Charteris, in *The Lancet*, some time ago, related excellent results in his experience from them. The records of a more than usually careful study of their influence have recently been published by Dr. J. G. Sinclair Coghill, of the Ventnor Hospital for Consumption, England.

The hypophosphites were prescribed in 100 cases chosen indiscriminately, 63 being cases of pneumonia, and 37 of tubercular phthisis. Eight grains each of the hypophosphite of soda and lime in an ounce of the infusion of cascarrilla, were administered twice a day after meals. During this treatment the various symptoms were carefully noted.

In regard to colliquative sweating, no good was done by the hypophosphites, and the same may be said of fever cough. The appetite was improved in 52, and the weight increased in 62 cases. The physical signs improved in 43 patients.

It was considered proved by a comparison of the cases that the hypophosphites have no claim to be considered a specific remedy for phthisis. They have, however, valuable tonic properties, improving the appetite, increasing the weight, and helping digestion. They are heat-producers, and should therefore be used only in the early or arrested stages of the disease.—*Lancet*, Sept. 6, 1879.

OVARIOTOMY AND COLD AFFUSION IN THE WOMAN'S HOSPITAL.—During the past ten months, from September, 1878, to July, 1879, Dr. T. G. Thomas has performed ovariectomy twenty-two times in this institution. Out of the twenty-two cases, cold affusion, by Kibbe's method, has been employed in nine, with the result of twenty-one recoveries, and one death. The death occurred in a patient sent to the hospital in a most forlorn condition, three weeks after delivery. The operation was resorted to as her only chance, as she was rapidly sinking, and she died from exhaustion. In this case cold affusion was not used.—*New York Medical Journal*, Sept., 1879.

PREPARATORY SCHOOLS OF MEDICINE.—A preparatory school of medicine and pharmacy has been established at Amiens, and will be opened in February, 1880. It offers a good example to England and America, both which countries are now discussing the deficiencies of preliminary education. There is already in this country a course of study at Yale College very well adapted to those intending to study medicine. It has not, however, the surroundings which would make it popular to medical students.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

W. L. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 11, 1879.

THE MECHANICAL TREATMENT OF POTT'S DISEASE.

II.

To the plaster-of-Paris jacket, as used by Dr. Sayre, there belongs another factor in treatment—namely, suspension. Suspension in Pott's disease is not entirely devoid of danger; yet it has been practised many hundreds of times without any apparent injury. Its chief value, doubtless, consists in the fact that it enables the surgeon to apply the jacket properly. It is claimed that by its use the pathological curve is diminished. In every deviation of the spinal column, be it antero-posterior or lateral, secondary curves are always formed, which are called compensatory. These secondary curves form above and below the point of disease, and tend to make that portion of the spinal column appear more deformed than it really is. It is possible, by extending the spine by suspension, to obliterate these secondary curves, and thus *apparently* diminish the pathological one, but it is doubtful if any real effect is produced upon it. The fibrous tissue ligaments and muscles about the point of disease hold the bones fixed, and prevent any sudden change of their relation. It has been demonstrated that by suspension the perfectly healthy spine can be lengthened. How much of the elongation of a diseased one may be thus explained?

In disease occurring in the cervical region the jacket is useless, except as a foundation for the bar that carries the chin-piece or jury-mast. Many think that, for disease in this region, the steel support, with an apron in front, is far superior to the jacket. The advantages of the plaster-of-Paris jacket are the ease with which the materials for its application can be obtained, the little experience required in comparison with that necessary for the fitting of a steel support, and its cheapness. It requires considerable experience (notwithstanding the statements to the con-

trary), to apply one properly, even by those who have used plaster-of-Paris bandages for other purposes; but, to one not accustomed to prepare and apply them, the difficulties are not few, and he will find out, to his sorrow, that excoriations will occur and the patient will complain. Dexterity in this, as in any other surgical application, is indispensable. We have seen cases in which the jacket has been put on, and in which it did not the slightest good;—not from any deficiency in knowledge, but from a lack of experience. The great claim for this material for splints is its cheapness, and if the objections can be overcome it will certainly prove a useful addition to our means of treating Pott's disease—chiefly in cases in which the disease occurs below the middle dorsal region. The steel support is no doubt a difficult apparatus to adjust. It requires not only time and mechanical skill, but considerable experience, and we suspect that this is one reason why so many do not think well of it. The idea that one can send to a surgical instrument-maker for a brace that will be of any use without any further adjusting, is based on a misunderstanding of the abilities of instrument-makers. This may account for the very unsatisfactory results that have followed the use of braces by the general practitioner, and one reason why the plaster-of-Paris jacket has become so popular—we had almost said fashionable. There is no question but that an apparatus that can be removed and permit of the simple rules of cleanliness being carried out, has so much in its favor. We do not wish to be misunderstood in this connection. We have no pet brace to advocate, nor do we wish to decry one method of treating Pott's disease or unduly praise another. We know that in skilful hands excellent results have followed the use of the plaster jacket; equally good results have been obtained by the use of felt splints; and years before the use of the plaster jacket was proposed, as good a result as we have ever seen by any method of treatment was obtained by a layman using a splint of cloth and shellac.

An impression has become somewhat current that, because a brace or a jacket has been applied to a case of spinal disease, the patient should be able to go about and engage in his plays or work as though he had no trouble, and that the treatment of these cases is a mere question of support. Nothing can be more harmful to one suffering from Pott's disease. The rule is, the more quiet, the better will be his chances of recovery. The fact is, that it is impossible to render a spine absolutely immovable when a patient is going about, no matter what kind of a brace or bandage is applied; and we must insist that as much rest shall be taken by our patients as is compatible with health, at least in the more acute cases.

It is a good rule to confine our patient to his couch for a week or more, and then gradually to permit of exercise in order that he may become accustomed to

his support. It should always be remembered that out-of-door exercise is secondary to absolute rest of the parts.

There has been much said and written of late on the necessity for extension in Pott's disease. It is a question whether, by any known apparatus, the spinal column can be held in a state of permanent extension; that is, that the bodies of the vertebrae can be pulled apart. What can be done, and is done by all forms of apparatus constructed on correct principles, is to throw the body back, and thus transfer the weight, as much as possible, from the bodies to the lateral masses. Those afflicted with spinal disease try in this way to relieve the pain, and this position is one of the most prominent symptoms of the affection. It is astonishing how little support, in some cases, is necessary to afford relief, especially in those in which the lower dorsal or lumbar vertebrae are involved. Simply fixing the spine in an erect position appears to be all that is required for some, while for other cases it seems almost impossible to give enough support.

In the treatment of spinal curvature, as in all other surgical diseases, that mode of dressing with which the surgeon is most familiar, and which has yielded for him good results, is generally the one he advocates. In discussing this subject it should not be forgotten that one may obtain good results from the use of a brace with which he is familiar, while another is equally successful with one of another pattern or construction. One may have more mechanical ingenuity than another, and of course can apply a brace or jacket better. In forming a judgment in this matter, it should be taken into consideration that there is no brace, jacket, or bandage that does not have some drawback. They all will, at times, chafe, and be uncomfortable; sometimes one form of support cannot be worn, while another can, and there are some cases in which no apparatus can be applied. There is no one spinal support that is applicable to all cases. We continually hear the claim made for this or that brace that it can be applied by any one. While deeply sympathizing with this desire, we cannot shut our eyes to the fact that experience in this, as in other departments, will always be indispensable to obtaining the best results. We do not believe that the treatment of Pott's disease will ever be so simplified that good results will follow any method of management in unskilled hands; he who has managed successfully the largest number of cases will be rewarded with the uniform best results. Of course there are very many cases that cannot be sent to a specialist, and to one who is forced to treat such a case any support that will meet the indications will prove of use, whether it be made of steel, plaster-of-Paris, paper, felt, or any other material. If the surgeon fully understands the principles upon which the treatment should be conducted, and has, or can avail

himself of mechanical ingenuity, he will either devise a new apparatus or modify some old one, so that he will adapt the surgical appliance to the special indications in an individual case, and will be rewarded with a commendable degree of success. If he does not possess these qualifications, his patient will suffer under his management, regardless of the plan of treatment adopted.

THE NEW HALL FOR THE ACADEMY OF MEDICINE.

THE dedication of the new hall of the New York Academy of Medicine was a notable event in the medical history of this city. By the liberality of Dr. Abram Du Bois, a fellow of the Academy, this elegant, convenient, and commodious building is now placed at the disposal of the profession. Together with the Academy building, of which it is an extension, it helps to realize the oft-expressed desire of many Fellows, of a general meeting-place of which the profession shall be proud; while the library, now numbering many hundreds of rare volumes, has a fitting habitation. In congratulating the profession of this city upon the full fruition of the plans which have been fostered for so many years, we must not forget to give the credit which belongs to the extra exertions of several individual members. We do not run the risk of being invidious in mentioning the untiring zeal of a former President, Dr. S. S. Purple, in the interests of the library, and of the extensive and valuable presentations which he has made to its shelves. Many others have done likewise in proportion to their means, and their liberalities will be duly remembered. These examples are worthy of imitation for the good of the profession at large, in making available under one roof the smaller libraries of individual members. In view of the library facilities which are now offered by the Academy, it is unnecessary to urge this method of donation. In regard to this point we may say, in passing, that we are pleased to learn that the friends of some of the deceased members are already calculating the propriety of making such gifts, and of thus building up monuments to their memory. New York is very much in need of a central medical library, and we know of no better place for it than the building of the Academy. It is true that the New York Hospital Library is a large and well selected one, and it is also true that the profession is free to consult its contents; but, belonging to a close corporation, and subject to its regulation, there is no guarantee how long the present arrangement may last. Besides, the profession is placed more or less under a feeling of obligation for the benefits enjoyed, which feelings will not be experienced in any home of its own, and where a voice can be had in its general government.

The opening exercises of the new hall were eminently appropriate. The speakers were carefully selected, and their remarks were well timed and duly appreciated by the large audience present. It is impossible

to resist the conviction that the success of the occasion was due to the indefatigable zeal of the present president, Dr. Fordyce Barker, whose donations of the magnificent bust of Spencer Wells, and of the handsome desk and elegant presidential chair, will be gratefully remembered by the society. His endeavors to prove that the Academy should be not only a scientific, but a social home for the profession of this city, were practically tested by the magnificent banquet which rounded out the exercises of the evening.

It can now be safely said that the Academy has truly waked up to the necessities of the hour, and its old friends and new will stand ready to uphold the hands of its worthy president and wish it God-speed.

THE GRADED COURSE IN BELLEVUE HOSPITAL MEDICAL COLLEGE.

The Bellevue Hospital Medical College has signified its intention, after the regular session of 1879-80, of modifying its plan of instruction so as to apportion to each one of three sessions certain divisions of the study of medicine—in other words, to have a graded course of three years. In addition to this change, preliminary examinations, or their equivalent, will be required of all students who expect to become graduates after the close of the session of 1879-80. It is gratifying to say that this is a long step in advance, and that Bellevue, in virtually taking the initiative in this city, deserves the best wishes of not only its particular friends, but of all who favor the right sort of progress in medical education. It is unnecessary to elaborate the details of the change, as it is sufficient that they are made to accord with the general principles of preliminary education, a graded course, and virtual increase of the time of study. Although every contingency as to character of study, time for yearly and final examinations, the kind of preliminary examination required, is apparently provided for, we are glad to know that the faculty is willing to make such changes or modifications in future as experience may render necessary. It is impossible to foresee the effect of such a change upon the size of its classes, but in the possibility of the latter falling off, there is a certainty in improvement of the qualifications of its graduates, and in the increase in the reputation of the school.

A CASE OF DOUBLE UTERUS AND SUPERFETATION.
—Dr. Sotschawar, of Moscow, reports the case of a woman, aged 26, to whom he was called on account of hemorrhage. Upon examination he found two vaginæ, each leading to a distinct uterus. The hemorrhage proceeded from both uteri, and was very considerable. After some manipulation an embryo of about one month was extracted from the left uterus, and three days later a fetus of three months from the right uterus. The observer asserts that this is the third case of the kind known to science. It may be remembered that Dr. Fordyce Barker, of this city, has had one such case in his experience.

Reviews and Notices of Books.

MATERIA MEDICA AND THERAPEUTICS: VEGETABLE KINGDOM. By CHARLES D. F. PHILLIPS, M.D., F.R.C.S.E.; Lecturer on Materia Medica, Westminster Hospital, London. Edited and adapted to the U. S. Pharmacopœia. By HENRY G. PIFFARD, A.M., M.D., Professor of Dermatology, University of the City of New York, etc. New York: William Wood & Company, 27 Great Jones Street. 1879.

This is one of the volumes comprising Wood's Library of Standard Medical Authors. It consists of a condensation of the original work of the author, such as brings it within the range of the present series, and the editor has also made it conform to the U. S. Pharmacopœia. Besides, it is to be noticed that the editor has given a brief description of a few indigenous drugs which are in rather general use, and also a few of foreign origin, such as jaborandi, etc. These are acceptable additions, and are designated by being embraced in brackets. The regular order consists in a presentation of the active ingredients of each article, its physiological and its therapeutical action, and its preparations and dose. With one or two exceptions, the sections on preparations and dose have been rewritten, so as to substitute official preparations (U. S.) for those of the British Pharmacopœia; and the doses are expressed in both apothecaries' weights and measures, and in the metric system. The work of the editor forms an important part of the volume, and brings it up to the latest knowledge on the therapeutical properties of the article considered.

MEMORANDA ON POISONS. By THOMAS HAWKES TANNER, M.D., F.L.S. Fourth American from the last London Enlarged and Revised Edition. Philadelphia: Lindsay & Blakiston. 1879.

The merits of this small book are too well recognized to require special comment. It is a convenient and comprehensive manual.

POCKET THERAPEUTICS AND DOSE-BOOK. By MORSE STEWART, JR., B.A., M.D. Second Edition. Revised and enlarged. Detroit, Mich.: Geo. D. Stewart. 1878.

This is a sort of an emergency book. We have heard of physicians who carry it constantly in their pocket with advantage. From this fact, and the not less important one that we have examined it and have found that it contains a good deal of practical knowledge, we commend it to the favorable consideration of medical men. It can be carried in a small pocket, and will be found to be a useful remembrance.

THIRTY-SIXTH ANNUAL REPORT OF THE MANAGERS OF THE STATE LUNATIC ASYLUM, UTICA, N. Y. For the year 1878. Albany: Charles Van Benthuysen & Sons. 1879.

This report was presented to the Senate of the State of New York, Jan. 15, 1879. Considerable space is devoted to a description of the method of heating and ventilating of the institution, as given by the superintendent, Dr. Gray, for transmission to the British government. This is followed by the treasurer's report, and then we reach the superintendent's report, which consists of a general review of the operations of the asylum during the past year. The experience of the superintendent has been, that it is just and wise to have the chronic insane taken care of in their own families, when it can be accomplished; yet he does not advise the adoption of the system of providing

for this class in a general way in private houses. To this is added the pathological report, embracing the work done under the direction of Theodore Diecke, special pathologist. Considerable space is given to a description of apparatus with which every microscopist is familiar, and which could have been more profitably occupied by a description of actual post-mortem and microscopical appearances found in the brain in the various forms of insanity. The pigmentary degeneration resulting from the absorption and deposition of materials in the protoplasm of the ganglion cells, furnished by the decomposition of emigrated red blood-corpuscles, is believed to possess more pathological significance than has hitherto been admitted. If what is known as insanity is characterized by pathological lesions, there is no better place to make the necessary examination to determine what those lesions are, than in large insane asylums. The State Lunatic Asylum, according to the report, is well provided with apparatus and specimens, and the profession of the State has a right to expect more of scientific observations than it has as yet received.

MANUALS OF HEALTH: ON HEALTH AND OCCUPATION.

By B. W. RICHARDSON, M.D., F.R.S., M.A., LL.D., F.S.A. London: 77 Great Queen Street, 4 Royal Exchange. New York: Pott, Young & Co. 1879.

This is an interesting little manual, divided into four parts. In the first is described the workers in community; in the second are indicated some of the injuries to health indirectly connected with the occupations of the different classes of workers; in the third the direct injuries to health and life are considered; and in the last part the author endeavors to point out some practical methods by which the lives of the different classes of workers may be rendered healthier and longer. It is a very readable and suggestive monograph.

VADE-MECUM OF EQUINE ANATOMY. For the Use of Advanced Students and Veterinary Surgeons. By A. LIAUTARD, M.D., V.S., Professor of Comparative Anatomy in the American Veterinary College. New York: Published at the American Veterinary College, 144 W. 54th Street. 1879.

This little book, containing nearly two hundred pages, is, in conformity to prescribed custom, designed to "fill a vacancy long existing." It is for the use of advanced students and veterinary surgeons, and consists of an abridgment of Chaveau's and Fleming's larger works, arranged to correspond to the professor's mode of teaching.

LABORATORY TEACHING; OR, PROGRESSIVE EXERCISES IN PRACTICAL CHEMISTRY. By CHARLES LOUDON BLOXAM, Professor of Chemistry in King's College, London. Fourth Edition, with 89 illustrations. Philadelphia: Lindsay & Blakiston. 1879.

This work evidently is intended for those who are beginning the study of practical chemistry in the laboratory. It has passed through three editions, and the student is now favored with the fourth, which contains some alterations; but the most important is the introduction of the formulæ representing the various chemical compounds described in the notes to the tables. The book will be found a valuable guide to the student in chemistry.

AMERICAN HEALTH PRIMERS: THE SUMMER AND ITS DISEASES. By JAMES C. WILSON, M.D. Phila.: Lindsay & Blakiston. 1879. Pp. 160.

This book treats of the summer, sunstroke, and heat fever, which latter is distinguished from other tran-

sient febrile states; summer diarrhœa and dysentery, cholera infantum, summer and autumnal fevers, summer colds and hay-asthma, the skin in summer and its diseases. The author writes as though he liked his subject, and has made the book a very interesting one.

L'ANNÉE MÉDICALE. Résumé des progrès réalisés dans les sciences médicales. Sous la direction du Dr. BOURNEVILLE, du *Progress Médicale*. Paris: E. Plon et Cie., No. 10 Rue Garangière. Pp. 417.

This volume is a very clear and satisfactory abstract of new ideas and discoveries brought forward during 1878. Controversies are sifted, and their final conclusions tersely stated; verbose descriptions by enthusiastic authors are condensed, and their essential points made more conspicuous. An effort has been made to sum up whatever is new and valuable in all that has been noticed in journals, monographs, reports of societies, etc., during the year. The descriptions are full enough to give a clear idea to the ordinary reader, and a good index of authors tells those specially interested where they can look up more carefully what particularly attracts their attention. The plan of the book deserves commendation in these respects. It is impossible to adequately review in a small space a work which is itself an epitome. We shall merely endeavor to give a general idea of the class of articles, calling special attention to only a few.

Under the head of anatomy are mentioned new investigations with reference to the origins and decussations of cranial nerves (M. Math. Duval), and new ideas of nerve-terminations developed by staining with .01 solution of chloride of gold (M. Ranvier). M. G. Hayem's anatomy of normal blood, and his theories in the matter of hæmatoblasts, are quite fully noticed. Careful measurements show the following: Normally, the sum of the calibres of bronchial tubes equals that of the original tube from which they arise; hence the respiratory passages constitute a cylinder, and not a cone (M. Marc. Lée). The right hemisphere the larger in a considerable majority of 300 brains (M. Le Bon). In 200 cadavers and 120 living patients the average capacity of the male urinary bladder exceeded that of the female organ by .07 (Hoffman).

The chapter on physiology is quite full. Specially striking are: Jacobson's branch of the glosso-pharyngeal, the motor nerve of the parotid gland (Heidenhain); the secretion of this gland, normally acid and not alkaline, as hitherto supposed (M. Astaschewsky). The acid principle of the gastric juice, the chlorhydrate of a feeble base (M. Richet). The retardation of the pulse in aortic regurgitation less than normal (M. F. Franck).

M. A. Kriedmann believes that he has demonstrated the depressor nerve of the circulation in the human being. The function of the semicircular canals is to give a notion of the three dimensions of space (M. Cyon). The telephone, microphone, and some other matters are described and discussed.

Under the head of medicine are pointed out new researches with reference to the germ-theory of fevers (Pasteur); tracheotomy with the thermo-cantery (Berger, Desprès, &c.); pneumonia an herpes of the lung dependent upon a primary neuritis of the pneumogastric (M. Fermet); diseases of the heart, liver, kidneys, and nervous system.

General Surgery is amply reviewed, and special chapters are devoted to the description of advances made in the study of diseases of the eye, ear, and genito-urinary tract.

In Obstetrics, utero-ovarian amputation, cephalotripsy, gastro-elytrotomy, and the question of the fetus being affected by medicines taken by the mother, receive special attention.

The section on therapeutics contains a long note on mineral waters, and observations upon the actions of *drosera rotundifolia*, *duboisia myoporoides*, *grindelia robusta*, *phytolacca decandria*, &c.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF PHILADELPHIA. Volume eighth. Containing the Report of the Proceedings from September, 1877, to July, 1878. Edited by J. HENRY C. SIMES, M.D., Lecturer on Histology in the University of Pennsylvania; Recorder of the Society. Philadelphia: Printed for the Society by J. B. Lippincott & Co. 1879. Pp. 225.

We gladly welcome another volume of the Transactions of the Pathological Society of Philadelphia, being the eighth report of its work. Its arrangement is the same as that of former issues, and reflects great credit upon the individual members of the Society, as well as upon the editor. The volume contains the reports on sixty-three specimens, besides a valuable paper on "The Causal Lesion of Puerperal Eclampsia," by James Tyson, M.D., consisting of over fifty pages that will well repay a careful perusal.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Oct. 2, 1879.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

DEDICATION OF THE NEW LIBRARY HALL.

THE Fellows of the New York Academy of Medicine and the invited guests met in the New Library Hall, and the meeting was called to order at 8.15 P.M. by the President.

After the reading of the report of the Committee on Admissions, by DR. E. H. JAMES, Chairman, DR. JOSEPH WIENER, Chairman of the *Committee on Subscriptions*, read his report, in which it was stated that sufficient money had been collected to defray all the expense of the new building and the improvements. He then read the names of all the subscribers.

DR. S. S. PURPLE, Chairman of the *Building Committee*, then read the report of that committee, in which it appeared that the receipts had been \$12,573, and the disbursements \$12,556. These figures included the \$3,000 placed to the credit of the Library Fund by reason of an additional donation of \$3,000 to the Academy by Dr. Abram Du Bois. The entire cost of the improvements had been provided for, and no debt had been created.

ADDRESS BY THE PRESIDENT.

The President then delivered the dedicatory address, in which he first referred to the reports just read, as containing a significance and depth of meaning which to thoughtful men must be more suggestive to the imagination, more comprehensive in its influence upon the younger members of our profession, who were hereafter to carry out what was only begun, than any fascination of rhetorical graces or oratory. There was in it an eloquence of results more moving and abiding than could be expressed by words. He

then paid a special compliment to the Chairman of the Subscription Committee, also to the Chairman of the Building Committee, who began his functions by creating the necessity for a Library Hall by his magnificent donation of what, in some respects, constitutes a unique library, and also expressed the pleasure and the appreciation of the Academy regarding the contractor and the builder.

With the dedication of the new Library Hall, it was hoped, there began a new era in the history of the New York Academy of Medicine, and that the rooms would give a central place where the profession would work for the advancement of science and the cultivation of the social graces which bind us in the friendly ties of a common brotherhood of a useful and honorable profession.

The founders of the Academy "budded better than they knew." There was good reason to anticipate that the young men in the profession, who were soon to fill the places and carry forward the mission of the medical profession in this city, would in mental activity, and useful and creditable work, far surpass their predecessors.

"Young men, we who soon are to give place to you, salute you."

The President then referred in glowing terms to what could be done by capacity for creating circumstances, by power of compelling everybody to work for the ends set out to be obtained, by breadth and scope of influence, as illustrated by him who began as an assistant surgeon in the U. S. Army, and through whose labor one of the most remarkable medical libraries in existence had been founded. Reference was also made to the great work which the same gentleman had done in connection with the organization and efficiency of a National Board of Health, through the agency of which we might confidently hope that in the future we might be spared from those terrible epidemics which bring distress and sorrow to some portions of our country. It was not for the sake of personal compliment that such reference was made, but for the purpose of enforcing the moral that if the genius and ability of one Billings could accomplish so much, what ought not to be expected for the future as the result of the active exercise of the combined talent, labor, and learning of such an organization as the New York Academy of Medicine.

The significant question was asked by the President, "May we not anticipate that we shall yet obtain the means of securing a home worthy of the city of New York, the great commercial—and, without wishing to dishonor Boston in the least, who had her worthy representative present—the great intellectual metropolis of the continent?" But to realize the hope we must demonstrate our worthiness to hold such a trust—one that would be as imposing as the noble edifices of the Royal College of Physicians and of the Royal College of Surgeons of London. Should any one, however, see fit to impose the trust upon them now, they would try and "bear the shock with manly courage."

MARBLE BUST OF MR. T. SPENCER WELLS.

The President then presented to the Academy, in the following appropriate language, a beautiful marble bust of Mr. T. Spencer Wells:

"A few months since a monument was erected in the town of Danville, Kentucky, in honor of McDowell, the surgeon who first successfully performed an operation which now must be conceded to be the greatest surgical achievement of the present century. It was a tribute due from the profession to one of its

great men. The operation is now accepted as one of the valuable additions to our means of saving many loved lives. It has been successfully performed in this country in many hundreds of cases by Atlee, Kimball, Dunlap, Peaslee, and others. Many of us can remember when it was denounced by the most prominent men in the profession, both at home and abroad, as an operation so hopeless and desperate as to seem unjustifiable, even in the face of surely impending death from ovarian disease. Yet, within a recent period, one of our number—need I mention the name of T. Gaillard Thomas—has performed the operation in twenty-two cases, with but a single death.

“The great work of our lamented Peaslee was dedicated to the memory of Ephraim McDowell, the Father of Ovariectomy, and to Thomas Spencer Wells, the greatest of ovariectomists. The latter has performed the operation 958 times, and, according to the calculations of Lord Selborne, late Lord High Chancellor of England, made in 1875, and based on five hundred operations, he must now have added to the life of woman in Great Britain but little short of 20,000 years of health, of usefulness, and happiness. His previous valuable contributions to general surgery have been comparatively forgotten in the great fame he has acquired as an ovariectomist. How it has happened, that one whose name is one of the chief glories of England as a benefactor to humanity, has not ere this received the highest honor which government ever bestows upon medical men, would be a mystery to us on this side of the Atlantic, did we not recall the fact that it has long been the custom of courts and of governments to confer the highest honors on those who are most successful in destroying life on a large scale, and not on those who save life. Feeling strongly, as I do, that it is a wise and good thing for the profession to cherish a warm admiration for those of our number who make positive contributions to our literature and to science, and who really accomplish great results, I beg leave to present to the Academy a marble bust of Mr. Spencer Wells. It was on exhibition at the last exposition of the Royal Academy of London, and received high encomiums from the critics of the artistic journals. In the number of the *British Medical Journal*, May 3, 1879, is an editorial on the Royal Academy, in which, speaking of this bust of Mr. Spencer Wells, it says: ‘This will certainly strike any one who examines it as a work remarkable for its artistic feeling and great realistic power. It is in the strongest sense characteristic, and indeed, is so powerful and remarkable a likeness as at once to challenge attention by its individuality and impressive resemblance. If any fault is to be found, it is perhaps that it is wanting in the look of genial amiability which distinguishes the great surgeon whom it reproduces, and modifies the otherwise stern, forcible features, which are here depicted with great power.’ While making no pretension as an art critic, I may be permitted to say it gives the expression which he wears when making a diagnosis. It must greatly add to the interest with which it is examined, when I add that it is the work of one of our profession, the artist being the eminent ophthalmologist, Richard Liebreich, who, in addition to the laurels which he has earned in ophthalmology, in science, and in medical literature, must now add those of success in sculpture, which hardly any amateur has ever attained and most professionals might envy.”

In connection with this, Dr. Barker loaned for the occasion a photograph of the beautiful home of Mr. Wells, a few miles from London, with an inscription by one of our most popular authors.

He also presented a beautiful presidential chair, with a reading-desk and table for the secretary.

In closing, he expressed the hope that the New York Academy would ever regard the occasion as a memorable era in its history, and would, from that evening, take a new departure which would be followed by a glorious career of usefulness and influence that would, in all future time, remain a monumental tribute to the high purpose, the wise forethought, and the noble liberality of Abram Du Bois, whose life-work had been specially devoted to the elevation of the profession, and improvement in medical education.

REMARKS BY DR. HENRY W. ACLAND.

The President then introduced DR. HENRY W. ACLAND, Regius Professor of Medicine, University of Oxford, who acknowledged heartily and sincerely the courtesy which never more kindly had been extended to him than on the present occasion, by requesting a stranger to begin the regular business of the evening immediately following the President's address. One objection he had to making remarks at that period in the meeting was, that it was not quite just to the senior member of the University of Oxford, then present, Dr. Gross, the great American surgeon, that he should not have been called upon first. However, with the President, he agreed that the two reports presented at the beginning of the exercises were full of interest; further, the President's address itself was full of matter for reflection, and he ventured the thought that the occasion was one of more than usual importance. For, hazarding the last remark, he made an excuse, believing it to be a just one, consisting in a picture of contrast between what he saw in this country, especially in the way of hospitals on a visit made twenty years ago, and what he had been permitted to see during his present sojourn among the American people. To reflect upon what this country presented twenty years ago, to read of the terrible struggle through which it had passed since that date, and to see how quickly the marks of destruction had been effaced, and ruined cities had been restored, was a matter of astonishment as well as of serious reflection and criticism. He then made special reference to what had been done in this country for the sick poor, and complimented the wealthy man, whoever he might be, who, out of his abundance, provided means for the amelioration of the suffering poor of the world.

With reference to the library, although having nothing of special interest to offer, he drew attention to what was the result of his observations during the last few weeks. First, must it not move us with some enthusiasm in looking forward to what the next generation will do with all the means at their command which this generation had provided for them.

Second, the great and vast work carried on by the medical profession in the United States was overshadowed by one difficulty, more or less present in almost all countries—the difficulty of producing an adequate combination among the numerous institutions. He, however, was not indisposed to think that in the future it will be difficult to contaminate the honorable members of the profession by those who are not entitled to publicly use the name physician. Medicine was a subject, not for statesmen nor for politics, but was a subject for humanity, and the progress of medicine concerned the entire world wherever sickness and suffering existed. With the existence of politics in his country they had nothing

to do, and they were making the attempt, and he thought there was no doubt of their success, to record all those who had a good medical education, so that with those they could have to do, and nothing at all with all the others.

Dr. Acland then passed to the subject of a National Board of Health, and was not prepared to understand how there should be any difficulty regarding the diffusion of knowledge from a central authority. No such difficulty was encountered upon the other side of the water, and to them it seemed incredible that such a difficulty should exist. Assuredly it was progress and benefit for all, and the hindrance of disease was one of the great duties of the medical profession. He then referred to our most valuable medical literature, and said that this country should have professorships created expressly upon the vast subject of comparative national health.

Finally, in the name of his countrymen, he thanked Dr. Barker for the honor he had done to his friend, Mr. Spencer Wells, and the Academy for the singularly pleasant illustration which it had given by this meeting of the unanimity of result which might be obtained by those who contributed of their wealth, and those who prosecuted their profession in the saving of human life.

MR. GEORGE W. CALLENDER sent a telegram announcing his inability to be present, on account of sickness.

The President then introduced the senior graduate of Oxford, and Honorary Fellow of the Academy, DR. SAMUEL D. GROSS, of Philadelphia.

Dr. Gross congratulated the Academy of Medicine upon the progress which it had made towards a great library institution, and wished it were in his power to add to the accumulation both in books and in money, but unfortunately he was nothing but a poor physician, a poor surgeon, and in that respect sharing the honor of most of those whom he addressed. He then recalled with melancholy feelings the name of Dr. John Watson, one of the founders of the Academy, and his object in so doing was simply to call the attention of the Fellows to the fact that the writings of the fathers of the profession are too much neglected at the present time. Who of us knew what we should of the writings of Hippocrates, Celsus, Ambrose Paré, Cullen, Gooch, the classical Pott, Richard Wiseman, John Hunter, and many others. He was quite sure that the time was not distant when great pains would be taken to present, either in the form of abstracts or the original works, the writings of the fathers of the profession to the rising generation. There were many useful kernels locked up in the writings of those men. He did not come with the view of making an address, but for the purpose of mingling with the Fellows of the Academy, and of shaking hands with and greeting some of his old friends, and, above all, to shake hands with his illustrious British cousin, Dr. Acland.

The President then introduced DR. JOHN S. BILLINGS, of Washington, D. C., who congratulated the Academy upon the evidences of progress by which they were surrounded. He gave a brief report concerning the Academy's other library, of which he had charge, and known as the National Medical Library at Washington. It contained about 70,000 volumes and about 100,000 titles for cataloguing. It was probably the best practical medical collection in the world, and that fact was due to the completeness of its folios of journals and periodicals. The value of a library depended very much upon the nature of its catalogue. The index catalogue of the National

Medical Library would give the names of authors and subjects, and there were probably about 8,000 subjects in the classification. The work on that catalogue was so far completed that no one man was necessary to its completion.

The President then introduced PROF. SHATTUCK, of Boston, late Regius Professor in Medicine in Harvard University, who made a few congratulatory remarks regarding the work which had been done by the Academy.

DR. WILLARD PARKER, SR., ex-President of the Academy, was next introduced. He gave a historical sketch of the origin and rise of the New York Academy of Medicine. Of the 250 Fellows forty-five years ago, only 22 were living. Its present position was such as gave it a controlling influence upon the general hygienic condition and public health of the city. At the close of his remarks Dr. Parker offered the following resolution:

"Resolved, That the opening of the new Library Hall on the present occasion is a demonstration of the wisdom and zeal of the founders of the New York Academy of Medicine, an institution that has for its object the elevation, the education, and the culture of the medical profession."

DR. AUSTIN FLINT, in seconding the resolution, expressed his congratulations upon the many occasions for joyfulness which were offered. In the first place, the Academy had secured a home. In the next place, it had secured a home through the bountiful munificence of a member of the medical profession, although he should not feel like offering any opposition to a further donation of a few thousands or even millions of dollars from one who was not connected with the medical profession. He congratulated the Academy upon the presence of its distinguished guests—Acland, Gross, Billings, Shattuck, and others; and finally extended hearty congratulations upon the future, of which the present was an earnest.

The resolution was enthusiastically adopted.

The Academy then adjourned to partake of a bountiful collation provided by the President.

Correspondence.

EXOPHTHALMIC GOITRE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Having under my treatment a case of exophthalmic goitre, I was naturally much interested in the article on that subject, in the number for September 20th, from the gentleman from Salt Lake City.

I should like to ask him whether he attributes his success to the monobromated camphor, quinine *s.*, oxide of zinc, aloine, digitalis, belladonna, ipecac, phosphide of zinc, nux vomica, or the unguentum atropia, ung. iodoform, chloroform, oil of lavender, or the application of tinc. capsicum (B. P.)—or, after all, was it the emplastrum belladonnae three by six inches? Or did *vis medicatrix natura* have anything to do with it? I am very sorry he did not try galvanism, for with that addition the treatment would have been complete.

As I said before, I am much interested, and would like to cure my patient, if possible, without the expense of sampling the entire materia medica.

EDWIN WALKER, M.D.

EVANSVILLE, IND., SEPT. 22, 1879.

EXPERIENCES OF A SUCCESSFUL PRACTITIONER.

III.

For some reason, my young friend, Dr. White, has the reputation among the people of being not over-busy. This is somewhat unfortunate for him, as most patients believe that a doctor who has not much business is good for nothing. But I tell all such that it is well for every youngster that he has abundance of time for study, as he will be so much the more capable in future. They all know how hard I studied when I was young, and how much I benefited by it.

It is astonishing how few can appreciate the necessity for this state of things. Not long since I had occasion to discuss the matter with the editor of our leading newspaper. He commenced the conversation by intimating that White was a rising man. I was delighted to hear this, as I saw my opportunity for doing a good turn. I told him that White was one of the most promising young men I had ever met. He was, in truth, a genius; otherwise, with the small opportunities he had for self-improvement and early education, he could never have amounted to anything. Still, I believe that there was a good deal in hard study, for Dr. White had really done more in that line since he put out his shingle than ever before. He was just commencing to see what he did not know, and now, not being bothered with outside business, he was with his books constantly.

As I always like to illustrate a point with a story, I told the editor some of my earlier experiences in practice when I relied entirely upon my books. This caused him much amusement, and with a twinkle in his eye, he remarked that I had not proved to him that White was a very safe practitioner, and that this studying business without practice was like learning to swim without going near the water. I saw the mistake I had made, and passed it off as best I could. I said to him, however, that there was no one's book knowledge that I would trust in preference to White's.

We then fell to talking about White's prospects, and, as two friends would naturally do, became quite confidential. In the course of the conversation I told him that I intended to do all I could for White, and that I would, irrespective of helping him, be glad to relieve myself of some of my large business. It is true no one helped me, and it was to hard study and hard work, with not even genius to help me, that I owed my success; still, I took a fancy to White, and I believed him to be too modest and too timid to help himself. As an illustration of White's timidity, or rather his want of self-reliance, I gave a detailed account of his first obstetric case. These cases I find are always interesting to a married man with an increasing family.

The case was one of ordinary labor in a primipara. The examinations were frequent, and the anxiety great. White took his Bedford's Obstetrics by the bedside and studied as he waited. Finally, before he knew it, the waters broke and the head came down. Here I drew a diagram to illustrate the anatomy of the parts. Finally, after waiting twenty-four hours, to the great neglect of his other patients (and here we both smiled), the child was born. With a sigh of relief, Dr. White said the trouble was over. In hurriedly cutting the cord, the end of the prepuce was severed; but as there was an hereditary tendency to club feet in the family, this was accidentally of some prospective benefit. The editor remarked incidental-

ly that he had witnessed operations of that sort, and had already written up the subject in his paper. But I must go on with my story. In due time the placenta was expected. The cord was presenting, and the mother-in-law was waiting. Soon Dr. W. imagined something wrong, and, as usual, sent for me. I was a hundred and forty miles away in consultation, and it was not until the next day that I returned, to find White still waiting for the placenta. When I arrived I made an examination, and found the after-birth perfectly loose and ready to drop out. Of course it was delivered in a moment, but I remarked that I never could understand why W. could allow his patient to be in danger of bleeding, and not have self-reliance enough to do what every medical student should have done under the circumstances. And yet White knew, I continued, as well what to do as I did, because he had often quizzed me in advance concerning not only all the probable, but improbable features of that case. As it was, the woman died of puerperal fever, without any apparent cause for it. Of course my former partner, who is a trifle jealous of White, said the result was owing to bungling treatment; but I assured the editor that this was not the case. He smiled; and I, out of politeness, reciprocated.

Just then White dropped in, looking tired, and feeling so, as he said, having been studying all day. I introduced him to the editor, and joked him concerning his extensive practice. This part of the conversation ended by my promise to send him five patients on the morrow morning. These, the editor facetiously said, W. could nurse for a month at least.

I believe I have not said anything of a new instrument of precision which I invented. Its description will come in very well here, as it had a great bearing upon my success in practice, and as I remember that I exhibited it on that evening to both the doctor and the editor. Of course I told the latter that it was not considered exactly professional to parade our wares before laymen, but inasmuch as he was a friend I knew he would keep matters to himself. The great difficulty with me was to give the instrument such a name as would convey an idea of its extended and varied usefulness. In fact, it would appear that nothing more was desired either by specialist or general practitioner. I remarked that in my experience with every "ill that flesh is heir to," I had felt the want of this instrument, and that for the sake of my profession and suffering humanity I was very glad that I had succeeded at least in adding my poor mite to the general stock. Here I discovered the editor taking short-hand notes, but he stopped as soon as I looked towards him, and I went on to say that the only impediment to the universal use of the instrument was the fact that no one understood how to adjust it but myself. However, it was my intention to do all I could to explain it to my brethren, so that they might profit accordingly.

The instrument is constructed of several parts, and extends, when the latter are adjusted, from the anus to the base of the skull. After I had taken the requisite time to put it together, I gave a detailed description of it to Dr. White, the editor being merely an accidental guest. I thought that the shortest way to a description of the apparatus was to give a history of its construction from the beginning. Accordingly I related to Dr. White a curious and obscure case of disease in a female, which commenced with an abrasion of the os and ended with leucorrhœa. It became quite necessary to examine the os, and so I thought

about inventing an instrument for the purpose. I saw "my instrument-maker," and he suggested that a new vaginal speculum might do the business. To make this part of the story short, he constructed for me my back-action, self-retaining pessarized speculum. This was in the course of the following description shown to Dr. White and several other acquaintances, who from time to time dropped in. It consisted of a tubular arrangement, expanded at the bottom, trumpet-shaped, and so split as to open when required. It differed from all other instruments of its kind, from the fact that the rim of the trumpet extremity was colored red. Several gentlemen to whom I showed the instrument were very much pleased, and I accordingly offered it to the *MEDICAL RECORD* for publication.

When I found what a good thing I had, I commenced to make improvements. By the way, I forgot to say that the woman, by the use of this instrument, entirely recovered.

I further stated that I found, by attaching an ophthalmoscopic mirror to the extremity of the speculum, I could direct the light to the internal os. By this additional appliance, I discovered that a very large majority of obscure cases of female disease are traceable to a slight abrasion of the mucous membrane at this point. By the use of a magnifying glass attached to the end of the mirror, these abrasions could readily be seen, as well as the extremity of the Fallopian tube. I related five cases in point, by way of illustrating the necessity of diagnosing this condition. So satisfactory were these examinations, that I was encouraged to increase the adaptability of my instrument. I found, in attempting with my catheter attachment to explore the Fallopian tubes, that as soon as I reached the fimbriated extremity, and was ready to grasp the ovum, the sphincter vagina relaxed and the speculum was no longer kept in place. I then explained the reason for this by referring to the wonderful sympathies of the vaso-motor system.

I accordingly devised an apparatus which extended behind, around the buttocks, and into the hollow of the back. This being accomplished, and the instrument being steadied, I could succeed, not only in getting the view I desired, but in securing spermatozoa in any part of the Fallopian tube. By this means I had been enabled, by examining the spermatozoa microscopically, to determine whether or no the patient's husband was predisposed to cancer, phthisis, impotency, neuro-asthenia, or insanity. In nine hundred and thirty-six cases which I had the opportunity of examining for suspected cancer I had found that eighty-five per cent. had a granular degeneration of the tail of the spermatozoa, corresponding in position to the fourth dorsal vertebra. In eleven hundred and two cases of suspected phthisis there was a fatty degeneration of the cervical portion of the tail; and in twelve thousand five hundred and seventy-nine cases of confirmed impotency there was a marked shrinking of the basilar portion of the head. The editor became very much interested at this point, but soon after lapsed into day-dreaming.

The results of these cases were so surprising that I was forced to attach a microscope to the mirror. This attachment, when advantage is taken of the hydraulic pressure of the bladder, can be so operated in connection with mirrors that the tissue of the ovary can be examined *in situ*. I then alluded to forty-three cases of prospective ovarian tumor which I had diagnosed by that means. I intend to report these cases at some future time, showing the advan-

tage of an early diagnosis and the use of my instrument.

At the risk of being considered too enthusiastic in my claims for this instrument, I described some other uses to which it was adapted. Its dilating powers were almost past belief. By the way, I stated that it, with slight modifications, could be used for the rectum, urethra, ear, throat, and with the Fallopian attachment had been employed in exploring the Eustachian tube and viewing the tympanum from the inside. I took occasion at this stage of the proceedings to say that I knew Roosa would be keenly alive to the advantages of this improvement. I may remark in passing, that since I sent him this part of my apparatus he has recommended all his ear cases to me. But this is only by the way. I further remarked that in a number of cases of stone, I had dilated the urethra so that I could introduce my hand into the bladder. This was an improvement on any method of procedure heretofore devised, inasmuch as when this could be done no crushing was needed. I explained, of course, how necessary it was to be careful in the manipulation, and to understand the anatomy of the parts, but in proper hands I thought the operation eminently safe. Willing to give White a chance to say something for himself, I asked him if he had ever done such an operation. To my surprise, however, he answered in the negative. Impressing him with the fact that the disease was a very common one, and sometimes not suspected by the patient, I alluded to my forty-ninth successful case.

I find that I am so much interested with this part of my subject that I cannot resist the temptation of continuing my description. The upper section of the apparatus extended from the lumbar region to the occiput, and supported an ear-speculum with ophthalmoscopic and thermo-electric attachments. Here, too, were a series of mirrors which corresponded in axes with those of the speculum, and which enabled the acute observer to examine the base of the brain and take the temperature of the pituitary body; at the same time he might be exploring the hitherto hidden recesses of the Fallopian tubes, or watching the progress of a calculus through the ureter. The latter could, however, never be done, unless the urethra was suitably dilated. I here exhibited a number of polished gas-pipes of different sizes which I used for the latter purpose.

By this time, although my audience was much interested, I confess that I was a little tired, but I concluded what I had to say by referring to the advantages of the back attachment as a spinal brace. I explained how all other braces were worse than useless, that plaster-Paris was likely to interfere with the secretion of pancreatic juice, and that my appliance was the only one founded on the correct principle of hydraulic pressure. I illustrated this on a hump-backed friend of the editor who happened to be present. As the evening was getting late, I only related one typical case of the many hundreds treated by me. This was a young man who had spinal disease and had not walked for many years. He was so feeble that when moved from one house to the other it was necessary to let him down through the roof. He was seen by several specialists, and all sorts of apparatus applied. In despair he sent for me, and after wearing my apparatus for a day he became so much improved that he joined a travelling circus. To prove this I read a very affecting letter from the patient, describing his great champion act upon the trapeze. The company then dispersed, and White and I were left to talk over professional prospects. * * *

THE NATIONAL BOARD OF HEALTH AND HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL RECORD.

In your issue of August 9th, "G." leaves the main point at issue in the beginning of this argument, and branches out rather extensively into the merits or demerits of the homœopathic school of medicine. I am sorry to see that he shows such a sectarian spirit; it is simply against this, and for *true* and *honest liberality* in medicine that I am contending. To answer "G." properly, I should necessarily have to enter into detail, and the question is such a voluminous one, that I fear it would take up too much of your valuable space. I should be very happy to correspond with "G." upon these points or any other, however, and if he will send me his address privately, through your hands, I will do my best to answer him. "B."

DETERMINATION OF SEX IN UTERO.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In looking over some of the back numbers of THE MEDICAL RECORD, I noticed an article headed, "The Determination of Sex in Utero," in your issue of Nov. 23, 1878, in which Dr. Joseph Mudd speaks of Dr. J. W. Swift and his theory of "conception preceding menstruation," and says that in this case the product will be female and *vice versa*, while Dr. Napheys has an entirely opposite opinion. Further on, Dr. Mudd says that he has experimented in all twenty-nine times, and in all cases has succeeded in the production of what he looked for—male or female. Now I have just one question to ask the learned doctors, and I think it will knock their theories into infinitesimal atoms: At what period did copulation or conception take place when the product was twins—one of them male and the other female? Awaiting an answer, I remain

Your obedient servant,

T. C. WAITE.

PITTSBURG, PA.

ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 28th to October 4th, 1879.

CLEMENTS, B. A., Major and Surgeon. Granted leave of absence for four months. S. O. 228, A. G. O., October 2, 1879.

BROWN, H. E., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to leave the Department and apply for one month's extension. S. O. 205, Dept. of Texas, September 29, 1879.

O'REILLY, R. M., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to leave limits of Department. S. O. 145, Dept. of the South, September 26, 1879.

GRAY, W. W., 1st Lieut. and Asst. Surgeon. When relieved from duty at Ft. Colville, W. T., to proceed to Vancouver B'ks, W. T., and report to the commanding officer for duty. S. O. 123, Dept. of the Columbia, September 15, 1879.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, July 1st to September 30th, 1879.

ELLINWOOD, C. N., Surgeon, granted leave of absence for thirty days from August 12, 1879. August 5, 1879. Ordered to rejoin his station. Sept. 10, 1879.

BAILHACHE, P. H., Surgeon, relieved from duty at the port of Baltimore, and ordered to New York to relieve Surgeon Ellinwood, granted leave of absence. August 6, 1879. Detailed as Chairman Board of Survey, to examine damaged property at the New York Marine Hospital. September 23, 1879.

DOERING, E. J., Surgeon, detailed as Chairman Medical Board of Survey, to examine into the physical condition of an officer of the Revenue Marine Service. September 22, 1879.

GASSAWAY, J. M., Asst. Surgeon, detailed as member of a Board to report upon the advisability of establishing a marine hospital at Port Townsend, Wash. Ter. September 18, 1879.

FISHER, J. C., Asst. Surgeon, relieved from duty at Cairo, Ill., upon the arrival of Asst. Surgeon Carter, and ordered to report for duty to the Surgeon-General, M. H. S. August 25, 1879.

BROWN, F. H., Asst. Surgeon, granted leave of absence for fifteen days from July 12, 1879. July 7, 1879.

GOLDSBOROUGH, C. B., Asst. Surgeon, assigned to temporary duty in charge of the Service at the port of Baltimore, Md. August 6, 1879. Granted leave of absence for twenty days from September 22, 1879, by reason of physical disability. September 19, 1879.

IRWIN, FAIRFAX, Asst. Surgeon, granted leave of absence for thirty days from October 7, 1879. Sept. 18, 1879.

GLAZIER, W. C. W., Asst. Surgeon, to proceed to Georgetown, S. C., as inspector. July 17, 1879.

DANA, C. L., Asst. Surgeon, detailed as member Board of Survey to examine damaged property at the New York Marine Hospital. September 23, 1879.

CARTER, H. R., Asst. Surgeon, relieved from temporary duty at the port of Boston, Mass., and ordered to proceed to Cairo, Ill., and assume charge of the Service, relieving Asst. Surgeon Fisher. Aug. 25, 1879.

HEATH, W. H., Asst. Surgeon, to proceed to New York for temporary duty. July 15, 1879. Relieved from duty, port of Georgetown, D. C., and ordered to report to Surgeon Ellinwood, port of New York. July 26, 1879. Detailed as Recorder, Board of Survey, to examine damaged property at the New York Marine Hospital. September 23, 1879.

The following candidates having passed the required examination, were appointed Assistant Surgeons, July 21, 1879:

O'CONNOR, FRANCIS J., of the District of Columbia, (assigned to temporary duty, port of Georgetown, D. C. July 16, 1878. Ordered to Baltimore, Md., for temporary duty during the absence of Asst. Surgeon Goldsborough, September 20, 1879), and

PORTER, FREDERICK D., of Michigan, (assigned to temporary duty at the port of Detroit, Mich., July 25, 1879. Granted leave of absence for fifteen days from September 6, 1879. September 1, 1879.)

TREATMENT OF PHLYCTENULAR KERATITIS WITH THE GALVANIC CAUTERY.—The galvanic cautery is enjoying great prominence now in surgical therapeutics. It has been pushed to the fundus of the uterus, thrust into the trachea, and has touched upon nearly every anatomical point between. One of the last and most delicate of its uses is that to ulcers of the cornea. M. Legroux, of Paris, has employed it with much success for such affections. He has a very fine platinum wire which can be made red-hot almost instantaneously. With this he touches the ulcer and then drops on a little warm water. There is very little pain, and the results are promptly favorable.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending September 27, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Sept. 27, 1879.	0	31	31	3	18	35	0	0
Oct. 4, 1879.	0	11	34	1	14	20	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from October 1st to October 7th, inclusive, was 52, and the number of deaths that occurred was 29. The total number of new cases for this year to October 8th is 1,403, and the total number of deaths, 480.

CRUDE PETROLEUM IN CONSUMPTION.—M. M. Griffith, M.D., Bradford, Pa., writes: "A great many 'new remedies' and 'new preparations' are now before the public for consideration and sale. I would call attention to an old one, and cheap one. It is a well-known fact that consumption is almost unknown in the oil regions of Pennsylvania—and that it is never developed here. The only reason for it is, that we are daily consuming more or less of it in the water we drink and use in cooking purposes. The water obtained from the best wells and other sources, if left to stand over-night in an ordinary vessel will be covered in the morning with a scum of oil. It is evident that most of us consume more or less of it. Consumptive persons coming here from a distance soon find speedy relief from their lung difficulties, and rapidly gain flesh and strength. The climate of Bradford is the most unfavorable; the days in summer very warm, the nights cold and damp, and the weather very changeable, and also much wet and disagreeable weather—so it cannot be the climate that effects the change. The crude petroleum, no doubt, would long ago have become a popular remedy in lung difficulties, if it had not been for its very nauseating properties. I have sent a supply of the crude oil of a semi-solid consistency, that accumulates on the suckers and casings of the wells, which is readily prepared into pills by incorporating it with any inert vegetable powder, to a number of physicians and hospitals, with a request to give it a trial in their cases of consumption. Sufficient time has not elapsed to give a full report, but thus far the report has been very satisfactory. About fifty per cent. of cures are reported of acute phthisis. It afforded much relief in all cases, and the report in most cases is that it effected cures in all curable cases. I do not claim that it is a specific, but that it will do more good in chronic lung troubles than anything yet suggested.

"The crude is rich in hydrocarbons, and seems to have a special action toward the lungs, relieving cough, hectic, night-sweats, and flesh and strength is rapidly gained. I have had it under trial now during the last twelve months, and I can state that my faith in it grows stronger the oftener I prescribe it. The pills are made of the usual size, three to five grains. Three to five pills daily, or when the cough is troublesome, or as the case seems to require; relief

is apparent from the first. The curable cases were, to all intents and purposes, as well as usual in less than three months; many much sooner."

Petroleum has been known from a very ancient period. Herodotus refers to wells existing in Persia from time immemorial. It was known by the Seneca Indians of our own country as Seneca oil, etc.

The United States Dispensary refers to it as a stimulating, anti-spasmodic expectorant and diaphoretic. It stands high as a domestic remedy in the oil-fields. It is to be hoped that the profession will thoroughly investigate the matter, and give their experience of this cheap and valuable medicine.

OPENING OF THE WINTER SESSIONS AT THE PHILADELPHIA SCHOOLS OF MEDICINE, DENTISTRY, AND PHARMACY.—In the University of Pennsylvania, Theodore G. Wormley, M.D., LL.D., Professor of Chemistry, made a general address introductory to the one hundred and fourteenth course of lectures in the medical department, and the second course in the dental department, on Wednesday, October 1st, in the hall of the medical department. A large number of the college alumni, as well as the faculty, were present.

On the same day, in the Pennsylvania College of Dental Surgery, Twelfth and Filbert Streets, Dr. Henry C. Chapman, Professor of Physiology, delivered the opening lecture of the course, and the Seventeenth Annual Session of the Philadelphia Dental College was opened by Prof. J. Foster Flagg, D.D.S.

Roberts Bartholow, M.D., LL.D., late of the University of Ohio, Cincinnati, and Professor of Materia Medica and Therapeutics in Jefferson College, delivered, on Wednesday evening October 1st, in the amphitheatre of the College Hospital, Sansom Street, above Tenth, the introductory lecture to the fifty-fifth session. He was introduced by Eilersie Wallace, M.D., Dean of the Faculty. After paying a tribute to the memory of his predecessor, Dr. Jno. Biddle, as a teacher, a writer, and a President of the American Medical College Association, Dr. Bartholow spoke at some length upon "The Present State of Therapeutics" (printed under head of "Original Lectures" in this number).

Upon the conclusion of his remarks, Professor Bartholow, who began, on that evening, his official connection as a member of the College Faculty, was warmly welcomed by the students, and presented by them with a handsome floral design and a service of crystal.

On the afternoon of the same day, Mr. Charles Bullock, Vice-President of the Philadelphia College of Pharmacy, Tenth Street, above Arch, briefly introduced to the students and faculty, Samuel Philip Sadtler, M.D., whose address reviewing the field of pharmacy and treating practically of the various chemicals, etc., opened the fifty-ninth annual session of the institution. This is Prof. Sadtler's first year as a member of the College Faculty, and the students, as a mark of their appreciation of his worth, presented him with a beautiful floral design. The college opens this session with a large class, which has been increased by 175 matriculates, who passed their examination yesterday.

B. B. Wilson, M.D., Professor of Principles and Practice of Surgery, delivered, on Thursday afternoon, October 2d, the general introductory lecture to the session of 1879-80 in the Women's Medical College of Pennsylvania.

(The medical class at Jefferson College this year numbers over 600 students, and the matriculating

class at the Medical School of the University of Pennsylvania has thus far 125 members.)

THE NORRISTOWN, PA., STATE HOSPITAL FOR THE INSANE.—Work upon the new State Hospital for the Insane, at Norristown, is progressing satisfactorily. All the buildings are under roof except the Administration Building, which has had the second story recently put on. Five of the ward buildings are virtually completed, including the steam-heating apparatus. The six boilers are nearly ready to be placed in position, and it is expected that steam can be turned on in another month. The floors of the wash-house and kitchen are to be of stone, instead of lithogen, with which the corridors have been paved. It has been thought advisable to secure gas from the Norristown Works, instead of building gas-works, and a contract has been entered into with the Norristown Works for a supply at two dollars per thousand feet. In view of the probable completion of the buildings by the 1st of December, the Secretary of State has been requested to notify the Governor that the time has arrived for the appointment of the trustees authorized by law.

THE NEWLY APPOINTED QUARANTINE IN THE DELAWARE RIVER.—At the weekly meeting of the Philadelphia Board of Health on Tuesday, September 16th, the joint committee, composed of the Lazaretto Committee, in conjunction with the officers of the Board, to whom was referred the proposition of the National Board of Health for the establishment of a quarantine station at the Delaware breakwater, presented their report. After reciting the facts that the proposition grew out of an application for a remedy to prevent boarding-house runners from getting aboard vessels coming up to the city, and after reciting the order itself, the report proceeds as follows:

"This order may be looked upon in three aspects. First. Does it meet the difficulties complained of by our Board? Second. Are there any grave objections to its methods? Third. If the latter is the case, have we any substitute to recommend?"

In regard to the first point, it is to be said that it entirely meets the difficulties complained of, so that vessels possibly infected would be completely isolated on the passage up the river to the vicinity of the present quarantine station, as desired.

"But, to come to the second point, the order provides for a new boarding station, and this appears to us an objectionable feature. According to the text quoted above, this is 'to be established at the mouth of the Delaware River, in the vicinity of the Breakwater, or at a point to be approved by the National Board of Health.' In the vicinity of the Breakwater, we are informed, there is no good anchorage for large vessels, ocean steamers for instance, and should such arrive there after sunset they would be obliged to cruise about all night, to their great danger, if the wind was easterly, and to the very great annoyance of the passengers under any circumstances. Farther up the bay the channel runs at some distance from the shore, giving no point where vessels could lay to as conveniently as higher up the river. No eligible site presents itself until within thirty miles of the Lazaretto, and when such is found, a new objection arises, namely, it would be burdensome to the commerce of the port to subject vessels to the delays and inconveniences of an additional boarding station. To learn the sense of those most directly interested in the commerce and trade of the city on this important question, we addressed notes to the Maritime Exchange, Commerce Exchange and Board of Trade, calling their at-

tention to the matter, and hoped to lay their views before the Board with this report, but, as yet, have not received them. The press has, however, spoken strongly against the project."

With reference to the third point, we would recommend, instead of the enforcement of the order, that the National Board of Health place a patrol boat on the river to run between Fort Delaware and the Lazaretto, the officer in command of which shall arrest any persons found communicating with inbound vessels subject to quarantine and bring them and their boats to the quarantine station, or simply to place an officer with the same powers on the revenue cutter doing duty on the river.

In conclusion, we offer the following:

Resolved, That a copy of this report be sent to the National Board of Health and that the honorable Board be respectfully requested to adopt either of the two measures above suggested as a substitute for their order establishing a quarantine of observation upon the Delaware.

The report was adopted and the Board adjourned.

NEW YORK AND NEW JERSEY QUARANTINED.—Portugal has issued a decree establishing quarantine against the States of New York and New Jersey. The decree is based, of course, upon erroneous information, and is very injurious to our commerce there, as well as being extremely absurd.

TREATMENT OF METRORRHAGIA BY PLUGGING THE CERVICAL CANAL.—Dr. Henry Bennett, in the *British Medical Journal*, describes the above method of treating metrorrhagia, it being one that he proposed nearly twenty years ago, and has frequently used since. He brings the cervix into view, and passes into it two or three small pieces of cotton tied by a thread, and then covers the whole cervix with two or three larger pieces, which are left in close contact with the os upon withdrawal of the instrument. In this way he rarely fails to stop the bleeding. The cotton is not treated with any styptic, as that is unnecessary. The cases which indicate this method of procedure are those in which hæmorrhage persists after the entire removal of local disease, in enlargement of the uterus, or where small polypi or polypoid granulations exist, or in the hæmorrhagic habit. The superiority of this method over that of distending the vagina with tampons is claimed to be very great.

FREE COURSE OF LECTURES ON DISEASES OF THE SKIN.—Dr. Bulkley will give a third course of lectures on diseases of the skin in the Pathological Amphitheatre of the New York Hospital, 7 West 15th Street, Wednesday afternoons, from 2.30 to 3.30 o'clock, commencing Wednesday, October 8, 1879.

CLINICAL LECTURE

ON A

TRANSVERSE LESION OF THE SPINAL
CORD IN THE DORSAL REGION.

DELIVERED AT THE PHILADELPHIA HOSPITAL,

By CHARLES K. MILLS, M.D.,

NEUROLOGIST TO THE HOSPITAL.

(Prepared for THE MEDICAL RECORD.)

THE patient, R. M——, is a mulatto forty-one years old. On two occasions, more than twenty years ago, he had chaneres, but he has never had any of the usual manifestations of secondary or tertiary syphilis. He claims that he was not a hard drinker and was not addicted to sexual excesses of any kind. He has no history of an injury. He comes from a long-lived family, and his general health was good until eighteen months ago, when, without any known exciting cause, he was taken with a feeling of soreness and weakness of the left foot, which soon extended as high as the left knee. In two weeks the right leg below the knee was similarly affected, and within a month he began to experience pain in the lower part of the back. For a few weeks before the parietic symptoms set in, the left foot would now and then feel numb and cold. Gradually the loss of power in his lower extremities and the unpleasant sensations in both legs and back grew worse. Occasionally he had involuntary twitching of the legs. Four months after the first positive parietic symptoms, he began to have the sensation of a band or girdle around the waist.

In six months from the first appearance of the sensori-motor symptoms in his left foot he was compelled to take to his bed. His legs were now quite helpless; he had constant dull pain in his back; the girdle sensation and a feeling of dragging in the abdomen were constantly present, and very annoying; passages from bladder and bowels were involuntary; and he had marked symptoms of abnormal reflex activity, such as a curious jerking of the knees, and retraction of the feet on slight irritation. He does not think that he had fever; he had no mental manifestations; no facial or ocular troubles; no symptoms whatever referred to the upper half of his body. No bed-sores made their appearance.

He remained in bed several months and took large quantities of iodide of potassium, from which he seemed to derive considerable benefit. Severe cauterization of his back was resorted to twice, and also apparently did great good. Under its influence the girdle sensation disappeared, the pains in his back improved, he partially regained control of his bladder and bowels, reflex excitement largely subsided, and his legs recovered some of their strength.

During the last six months he has made some improvement under the use of specific and tonic treatment.

Let us examine him as he sits in his invalid chair, for he is unable to stand or to bear any weight on either leg. His general appearance is good; his face not expressing any special care or suffering, and his body and limbs not showing any marked wasting. Nothing wrong can be detected about the head; his sight, hearing, and other senses are unaffected. The only symptoms which he has had in the parts of the

body above the waist have been feelings of numbness or stinging in the little and ring fingers of the left hand; several months since he had sensations of this kind which would last two or three hours and then pass off, to return again after the lapse of hours or days.

In answer to my questions, he says he has no longer the sensation of a cord around the waist. When it was present—a point of some interest in locating the level of his myelitic lesion—it was immediately below the umbilicus. Examination of the spine by pressure, percussion, heat, and cold, and electrical tests, elicits no response—no shrinking or other manifestations of pain. He now has fair control over his bowels and bladder.

With him, as with many other similar cases, I find considerable difficulty in making quantitative determinations in regard to sensation. Touching his feet or legs gently at any part with the points of the aesthesiometer, twitchings are produced, as if both sensation and reflex action were exalted; at the same time his answers in regard to the distance apart of the two points of the instrument are very irregular and confusing. He declares, however, that he feels the impressions very acutely. Sensibility in the right leg and foot appears to be slightly better than in the left. No retardation of conduction for pain, touch, tickling, pressure, or temperature, can be determined by the ordinary tests.

Both lower extremities are almost absolutely paralyzed, a little power being retained in the left limb. As helpless as are his legs, however, they do not show any marked trophic or vaso-motor changes; wasting is comparatively slight, and no ischaemia, eruptions or bed-sores are present.

Electro-contractility is retained; active quiverings and contractions are produced with a faradic current of moderate strength. I am also able to demonstrate on this patient the so-called "diplegic contractions." Applying one moistened rheophore to the spine in the dorsal region, and the other along a nerve-trunk in the leg, contractions are caused not only in the muscles on which the electricity is directly acting, but also in those of the other limb; sometimes a strong current applied to one thigh will cause contractions in the corresponding muscles of the other side. These electrical phenomena, as also the reflex manifestations to be next considered, probably indicate some vascular excitement at the seat of lesion, and also point to a nearly complete transverse destruction of the cord.

This patient has already furnished us with several studies of much interest, but his most striking symptoms have reference to reflex action. In cases of spinal disease, the reflex activity of the cord may be normal; or, what is more likely, it may be either diminished or increased. Reflex action may be studied clinically in several ways. Irritation of the skin is an old and common method of investigation; we can resort to tickling, or to pricking with a needle or the compass-points. The soles of the feet are favorite areas for these experiments; but the palms of the hands, the belly, the thighs, and, indeed, in pathological cases, almost any part of the body affected by the spinal lesion will answer. Annoying reflex actions sometimes take place during the performance of such operations as catheterization, but I would hardly recommend the use of the catheter for studying reflex phenomena. Within a few years the so-called tendon reflexes, or tendinous reflexions, have been attracting a large share of attention. These reflexes are certain responsive movements which are called forth by mechanical irritation of tendons; by striking, for instance, the patellar ligament, the tendon of the quad

riceps extensor, the tendo-Achillis, etc. They have been carefully studied by Westphal, Erb, Gowers, Hamilton, Gray, and others.

Touching the sole of either foot of this patient causes the foot and leg at once to be drawn up somewhat violently; and gently pricking the skin with the compasses at almost any point on the legs causes active but irregular muscular twitchings or jerking of the entire limb. The skin reflexes are exalted.

Taking up the tendinous reflexions, I will first direct your attention to the patellar ligament, the most convenient point for investigating these phenomena. One leg can be thrown over the other so as to elevate the foot from the floor, or, what is better, the patient can be seated on a table, or the side of a bed, so as to allow his legs to dangle freely. The limb should be perfectly relaxed, and if the individual has any will-power over it, he should be directed to not exercise this volition, but to keep his mind as nearly as possible in a negative condition.

I lightly tap the ligamentum patellæ, first of one side and then of the other, with a single finger, and a quick forward propulsion of the foot and leg results; repeating the tap again and again, the movement is rendered more violent and tends to become a continuous but irregular vibration. With the ulnar edge of the hand I next strike the tendon of the quadriceps extensor cruris, and, with a jerk, the leg is again extended upon the thigh. Percussion of the tendons of the adductors, of the gracilis, and of the tibial muscles, etc., causes a motor response, although not of as violent a character as that elicited from the patellar and quadriceps tendons. A curious reflex in this case is one which I bring out by tapping the testicle, and along the line of the spermatic cord near the pubis, a slight retraction of the testicle takes place, probably due to the action of the remaining fibres of the cremaster muscle. Percussion along the spine of the tibia, you also observe, calls out the reflex action of the quadriceps almost as well as striking upon its own tendon.

Placing my hand under the ball of the patient's foot, I suddenly press the foot upward. The result is remarkable. At first the foot is affected with a general tremor which passes upward; a moment later it begins a sort of wagging movement; soon the entire leg is involved, and is tossed about in the most fantastic manner. Performing the same experiment upon the other foot, both limbs are now the victims of this irregular shaking, jerking, and swinging, better than chorea conveying the idea of a true "insanity of motion."

The act of forcing the fore-part of the foot upwards, in the manner which I have just shown, is what is known as "passive dorsal flexion." The movement which results is the foot- or ankle-clonus, or "foot-phenomenon" of Westphal. You could not have a better example of it. The tendo-Achillis is put upon the stretch; it is irritated by the state of tension into which its fibres are thrown; exaggerated reflex actions are called forth, and these cause alternate flexions and extensions, due to successive contractions and relaxations of antagonistic muscles. The phenomenon is similar in many respects to that described by Brown-Séguard and Charcot as spinal epilepsy. In order to call out the movement, it is sometimes necessary, in addition to forcibly flexing the foot, to strike upon the tense tendo-Achillis with some object, but here this is not required; mere flexion of the foot starts it on its convulsive round.

The symptoms presented by this case would seem to point, with scarcely a doubt, to a transverse lesion of the spinal cord above the lumbar enlargement,

probably in the mid-dorsal region. The history of the case is that of a gradually supervening paralysis of both legs, with the cincture sensation, pain in the back, paralysis of bladder and bowels which partially passed off, and abnormal reflex activity. The lower extremities, although paralyzed, are not markedly wasted; they exhibit neither vaso-motor or trophic changes of any moment, and their muscles respond well to electricity, showing that the lumbar enlargement of the cord—the region in which originate the important nerve-trunks of the lower limbs—remains comparatively intact. The position of the cincture or girdle feeling, at or just below the umbilicus, would also indicate a lesion in the middle, or from the middle toward the lower end of the dorsal region. A careful study of this symptom alone will sometimes enable us to arrive at a tolerably accurate idea of the seat of a spinal lesion; it probably indicates the highest sensory nerves involved in the lesion. In cases of dorsal lesion, also, partial control of the bladder and bowels is not infrequently regained, as in this patient. The slight numbness or stinging experienced for a short time in the left little and ring fingers was probably caused by a temporary extension upwards of congestion or inflammatory action from the main lesion to the lower cervical region. The impossibility of any permanent injury to the cervical cord having taken place is clearly shown by the absence of symptoms which would indicate involvement of the brachial plexus, and also by the fact that respiratory, circulatory, and oculo-pupillary manifestations are wanting.

A theoretical explanation of the abnormal reflex actions exhibited in this case is not hard to give. Reflex centres are probably situated in the gray matter of the spinal cord, and these are dominated by the brain. Excessive reflex may be due to unnatural excitability of these, or to a calling off of the restraining or inhibitory influence of the cerebrum. The apparently spontaneous movements experienced early were probably indications of an acute or subacute inflammatory condition. At present the same cause may be partly operative; but mainly the reflex actions are wayward and excessive, because a limited but destructive lesion has separated the lower reflex spinal centres from the inhibitory apparatus of the brain.

It is much easier in this case to locate the lesion than it is to arrive at a positive conclusion as to its nature. The man has a clear history of syphilitic infection; specific treatment has been of service, and it is altogether likely, therefore, that you have here some form of syphilitic disease affecting the spinal cord. It is not necessary to the explanation of the symptoms for the disease to be intramedullary. Any pathological condition or process that would cause limited compression and secondary myelitis of the mid-dorsal cord might give rise to the phenomena here manifest. A careful study of the history of the case leads to the idea of a gradual compression or destruction of the cord from its anterior surface. Vertical sclerosis, atrophy of the gray matter, vertebral periostitis or exostosis, caries, meningitis, and tumors of the dura-pia mater, or of the cord, are among the spinal affections which may owe their origin to syphilis. An intra-meningeal growth would account pretty satisfactorily for all the symptoms.

The treatment so far instituted in this case has been chiefly anti-syphilitic in character. A year ago he took iodide of potassium with advantage. Since coming into my hands mercurial inunction has been pushed until constitutional effects were produced, and more recently he has been again taking iodide of

potassium. The actual cautery has also been used on several occasions with apparent benefit. The method of cauterization which I prefer, as you well know, is the superficial burning with a white-hot iron. I have found in this, as in very many cases of chronic spinal disease, occasional dry or wet cupping of the spine to be of service. Galvanization of the spine has also been tried, but does not appear to have done any perceptible good. Faradization was used for a short time with advantage, but ceased to be of service after a few applications. Tonics have also been given. The patient is undoubtedly in a better condition now than he was several months since. Then he was confined to his back, he suffered from rachialgia, his passages were involuntary, etc. Now he is able to be up in a chair, and all of his symptoms have abated in intensity.

INTERNAL URETHROTOMY AND LITHOTRIPSY

AT THE SAME SITTING, IN A PATIENT 79 YEARS OF AGE; WITH REMARKS ON RAPID LITHOTRIPSY, AND ON THE EVACUATION OF DETRITUS FROM THE BLADDER.

By J. W. S. GOULEY, M.D.,

PROFESSOR OF DISEASES OF THE GENITO-URINARY SYSTEM IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF NEW YORK, SURGEON TO BELLEVUE HOSPITAL, ETC.

FOR the facts connected with the previous history of the case detailed below, I am indebted to Dr. Ramon L. Miranda, who obtained them from the patient. I take great pleasure here in making my acknowledgments to Dr. Miranda for his valuable aid in the management of the case.

Doctor —, an eminent surgeon of Havana, Cuba, seventy-nine years of age, of spare build, but of great energy, has of late years become invalided on account of dysuria and of vesical irritation; but he has nevertheless been able to perform his usual labors, and his general health has suffered but little. Without antecedent urethritis, he has had symptoms of urethral stricture ever since 1836, when J. Cloquet, of Paris, detected a narrowing in the pendulous portion of the urethra, for which, however, nothing was done, and he seldom suffered more than ardor in urination, principally during the night, or after having taken more than his wonted exercise.

On the 30th of June, 1878, after an obstinate constipation of four days, he was seized with complete retention of urine, from which, in twenty-four hours, he was relieved by the introduction of a gum catheter No. 3 (French scale), which was kept in for three days. Its removal caused much pain, owing to alteration of its surface by the urine. It was replaced by another catheter, which was renewed every day, but retained only from four to eight hours. This was continued eighteen days, and the bladder regularly irrigated with sundry solutions—of acetate of lead, phenic acid, etc. Baths, cataplasms, leeches to the perineum, etc., were also employed. From that time he began to experience, during each act of urination—which was unduly frequent and difficult—much pain at the anus and in the urethra, especially in the fossa navicularis, and the urine became purulent. These symptoms have ever since persisted with more or less severity. He has

never had pain in consequence of riding on rough pavements, and twice he rode one mile in a carriage to see me, without suffering the least inconvenience. He had consulted many surgeons, most of whom were of opinion that his troubles were caused by prostatic enlargement and urethral strictures. About a year before I saw him, gradual dilatation was suggested, and then internal urethrotomy, which was done in September, 1878, with Maisonneuve's urethrotome. The incision made was very superficial ("nothing more than a scarification"), and a "straight metallic sound, No. 11 (French), was introduced with much force—causing intense pain—without entering the bladder." In the course of an hour the extravasated blood in the surrounding connective tissue formed a tumor on the right side of the body of the penis, extending to the pubes; this hematoma gradually disappeared, but left at the base of the penis an induration which has remained very tender to the touch, and which has seemed to the patient to be the starting-point of the great pain he has suffered while urinating.

Continuous dilatation was afterwards tried with Beniqué's catheters, from No. 6 to No. 1, changing the instrument every twenty-four hours. During this course of treatment of twenty-one days there was the most profuse suppuration, and finally on the twenty-first day a free hemorrhage. From that time until July, 1879, a sound was introduced every second day, but without the slightest benefit. The only relief he experienced was from frequent vesical irrigations with tepid water. Meanwhile the bladder was several times explored, but no calculi were detected; still the patient himself thought that there might be stones. Once the bladder was injected with a strong solution of nitrate of silver on account of "recto-vesical neuralgia." This he thinks made him much worse. He finally concluded to come to New York to be treated, and on July 21, 1879, called upon me at the suggestion of, and with, Dr. Ramon L. Miranda. I detected, with a soft bulbous bougie, three urethral strictures—one in the fossa navicularis, the second at two inches and a half, and the third at four inches from the meatus; this last admitted No. 6 (Eng.). I made dilatation to No. 8 steel sound, and, wishing to ascertain whether he could empty his bladder, I passed a No. 6 (Eng.) Mercier soft catheter, and as soon as it entered the bladder grated against a hard body, which I thought was a stone; very little urine flowed—not more than an ounce—and no bleeding ensued. Rectal exploration revealed hypertrophy of the prostate to double its normal size. There was no median prostatic hypertrophy, as afterwards ascertained. My mind was made up as to what should be done, but as the patient was very nervous and timid from his previous sufferings, and as, besides, he required preparatory treatment, I said nothing of the necessity of a cutting operation, but simply advised daily vesical irrigations, and the introduction of sounds partly to dilate the strictures, partly to blunt the extreme sensitiveness of the urethra, and enable me the better to explore the bladder. Full doses of quinine were prescribed. On the following day I passed a No. 8 sound, and as it entered the bladder its point came in contact with a calculus. Dr. Miranda took the sound, and also felt the stone. I then introduced a Mercier catheter and irrigated the urethra and bladder with a solution of bicarbonate of soda. This was repeated daily until August 5th. Twice during that time I was obliged to push back with the sound a calculus which was engaged in the urethro-vesical orifice, where it had been creating much irritation for several hours.

Nos. 9, 10, and 11 sounds caused much pain, which was, however, well enough tolerated, and no rigor, no hæmorrhage, at any time followed the use of these instruments.

He rested each day, but was able to call at my house to be catheterized. I thought further attempts to dilate the strictures out of the question, as they were extremely resilient, and advised internal urethrotomy and lithotripsy at the same sitting, and the 7th of August was appointed for the day of operation. A cathartic on the 6th, and an enema on the morning of the 7th were ordered. Assisted by Drs. Miranda, Lewis, Roberts, Sayre, Jr., and Goodwillie, who administered nitrous oxide, I made free division of each of the three strictures, from behind forward, with Civiale's urethrotome, and was able to introduce a steel sound ten millimetres in diameter; then, with a flat-bladed lithotribe, seized and crushed four phosphatic calculi, one of half an inch, and three of three-eighths of an inch in diameter. I also caught and crushed seven fragments (some of these may have been small stones) each of a quarter of an inch in diameter, and four of one eighth of an inch—fifteen seizures in all, including the four stones. The lithotripsy proper occupied less than five minutes, during which time the lithotribe was twice introduced, and brought out charged with detritus. I noticed, while passing the instrument, that its point became engaged in the mouth of an old false route on the right side in the sinus of the bulb, but by altering its direction it went in without further impediment, and in the subsequent introductions of all instruments I always succeeded in avoiding this cul-de-sac. There were columns in the bladder, from hypertrophy of the muscular coat. Aspiration with Bigelow's elastic pear was then made, but very little detritus was brought out. The entire operation—that is to say, the exploration, the urethrotomy, the catheterism, the aspiration of detritus, etc., lasted twenty-eight minutes. There was very little loss of blood, and the immediate effects of the anæsthetic passed away rapidly. In two hours the bladder was emptied by means of a catheter, and in three hours after, catheterism was again done with a No. 14 (Eng.) Mercier gum catheter, which was then plugged and retained for seventeen hours. Every three hours the plug was removed, and the urine which flowed was at first fetid and tinged with blood, but soon became clear. The catheter was replaced by another, which was retained only seven hours. There was some tumefaction of the penis, which on the fourth day entirely disappeared. He was up on the seventh day. Nine grains of detritus had been obtained, partly from the beak of the instrument, partly by aspiration, and in the first two or three days eight grains came away through the catheter. Probably an equal quantity was lost, as he urinated spontaneously several times. Free doses of quinine were administered during the whole treatment, and the bladder was frequently irrigated with a solution of bichloride of soda. As on the day he got up (Aug. 14th) he had a considerable amount of irritation at the urethro-vesical orifice, and the old ardor at the anus and in the fossa navicularis, I made an exploration of the bladder with a flat-bladed lithotribe, and seized and crushed three fragments (or small stones) of a quarter of an inch in diameter, brought out a beak full of detritus, and, with what was passed through the catheter, obtained in all eight more grains (the detritus was never weighed until it was quite dry); at the end of two days no more detritus came away. On August 19th I sent him to take a ride of four miles on rough pavements; when he

returned the urine was slightly tinged with blood, and he felt the old pains in the perineum and urethra. On the 20th I made a third exploration of three and a half minutes, and could find only two fragments, one of a quarter, the other of one-eighth of an inch, and brought out a beakful of detritus, which, when dry, weighed three grains. The total amount of detritus collected weighed, when dry, twenty-eight grains. After this he had no more symptoms of stone. Still, in two days I made another exploration, and in two more days a final and most thorough examination with the lithotribe, without finding any trace of calculous concretions. Steel sound No. 15 (nine millimetres in diameter) had been introduced every second day, and he was soon able to pass it himself. During the whole of this time he never had a rigor, nor indeed any other untoward symptom. On account of some remaining urethro-cystitis, I several times irrigated the whole urethra and bladder with a very weak solution of nitrate of silver, which produced the desired effect.

Before his departure he was able to urinate in a large jet, which was well propelled for a man with a large prostate, and on several occasions, immediately after urination, I passed a catheter, and only two or three drachms of urine came away. The patient sailed for Havana on Sept. 5th, in better condition than he had been for a year at least, promising to empty his bladder twice daily, and to make an irrigation with the bichloride solution, and in case the urine should become alkaline, to use acetate of lead, as the principal means of preventing the recurrence of phosphatic calculi. Once a week he is to introduce his No. 15 steel sound, to prevent recontraction of the strictures.

COMMENTS ON THE CASE.

I have selected for comments a few from the many points of clinical interest which this case possesses.

The patient was known to have an ancient urethral stricture, which had contracted so slowly as to give rise to but slight dysuria at the end of forty-two years, and when at last (in June, 1878,) retention of urine occurred, it was caused not by the stricture, but very distinctly by acute engorgement of the already hypertrophied prostate, resulting from the obstinate constipation of four days.

The two courses within a year of continuous dilatation had the effect of making the strictures worse, more resilient, though a certain amount of dilatation was maintained by frequent catheterism. Nevertheless, in the end of July I found it impossible to dilate them beyond No. 11 (English scale). This, with the great sensitiveness of the canal, rendered ordinary lithotripsy impracticable. It does not appear that cystitis existed prior to June, 1878; this complication was provoked by the presence of the catheter, which was retained three days, and from that time date the vesical symptoms which became so distressing in 1879.

I have every reason to think that the age of the stones which I crushed in August, 1879, was thirteen months, and firmly believe that their nuclei were the concretions which fell from the retained catheter at the moment of its withdrawal. But it is known that such phosphatic calculi grow rapidly, and it might be asked whether in a year's time they would not have attained a greater size? Without intervention, most decidedly yes; they would have been each at least one inch in diameter but for the fact that the urine was drawn off and the bladder for a long time irrigated every day, and occasionally too with a solu-

tion of acetate of lead, than which there is no better reagent for the disintegration of phosphatic calculi. This, it seems to me, is a sufficient explanation of the diminutive size of the stones.

Two symptoms of stone were wanting in this case: frequent hematurias, and pain while riding in a carriage; but these symptoms are often absent in the aged. Two operations were indicated: internal urethrotomy and lithotripsy. Thinking that lithotripsy would be impracticable without the urethrotomy, principally on account of the great urethral irritability, I decided to combine the two operations, and, with the aid of an anæsthetic and of aspiration, hoped to be able to do them both at a single sitting of not more than twenty minutes, but succeeded in extracting only a very small amount of detritus, and two additional sittings were necessary to complete the operation. These sittings were, however, very short and well borne, though it was difficult to seize the last fragments owing to the bladder being hypertrophied and columnar, and neither anæsthetic nor aspiration was used. The aspiration was here a failure, but I am sure that if I had persisted and made another introduction of the lithotribe I would have succeeded in removing the entire detritus; but I did not wish to prolong the sitting.

In another case I also failed to extract the detritus by aspiration, but it was because there existed a false route in the deep urethra which absolutely prevented the passage of any of the catheters belonging to Bigelow's aspirator. The lithotribe was, however, always introduced with ease and all the detritus evacuated through one of Tiemann's India-rubber catheters. Six sittings were required, and the patient made an excellent recovery without having suffered the slightest untoward symptom.

In a third case, on account of a small oxalate of lime calculus which had caused inordinate vesical and urethral irritation, I employed anæsthesia, and aspiration with Bigelow's bag, and at one short sitting completely relieved the bladder of the detritus made by several crushings of the hard concretion.

Long sittings are justifiable in many cases, but I would not be willing to resort to them in aged persons, such as the patient of seventy-nine years who is the subject of these remarks; in like cases I believe that several (three, four, or five) sessions of one or two minutes, without anæsthesia, are safer than a single long one of an hour or more, with the aid of an anæsthetic.

RAPID LITHOTRIPSY.

Among the requisites for the successful performance of lithotripsy is an ample urethra, or one that can be safely and easily rendered so, that the detritus may be expelled or extracted without inflicting serious injury to the canal. This operation was for a long time believed to be contra-indicated in cases of narrow or resilient strictures of the deep urethra; but since Heurteloup gave the first impulse to rapid lithotripsy and showed its applicability to such cases after dilatation or internal incision, a change of opinion has gradually come about, so that at present it may be considered good surgery, in case of obstinate stricture complicating a calculous affection, to make division or internal urethrotomy, and at the same sitting to introduce a lithotribe, to crush the stone, and forthwith to extract all the detritus or the greater part of it, without molesting the wounded urethra by gravelly matter or by urine.

I beg leave to take this opportunity to state a few facts bearing upon the history of rapid lithotripsy,

and also of the aspiration of detritus from the bladder, as they are now both attracting the attention of lithotriptists. In tracing back the history of the sundry methods of lithotripsy carried out as they were at first by ponderous engines—so to speak—with drills, saws, scrapers, and many other devices to reduce vesical stones to dust and small fragments, at a time, too, when anæsthetics were not used, it has seemed to me marvellous that this operation should have so formidably rivalled lithotomy, and should be what it is, and no longer militant. The truce between the two ended in its becoming firmly established as a surgical procedure of the greatest value, equal to lithotomy and often combined with it.

To bring lithotripsy to its present state has required the best thoughts and labors of many. No one man has accomplished the task. Civiale, Amussat, Leroy, Brodie, Jacobsen, Heurteloup, Mercier, Fergusson, and others of the same period, have performed the bulk of the work, and have established the great principles by which we are now guided. Minor details, but no new principles, have since been given, and from time to time modifications and improvements of existing instruments have been made by faithful students of lithotripsy. From an early period of the age of lithotripsy, nearly all of those surgeons above named began their endeavors to simplify the operation and the instruments necessary for its execution, and to reduce it to one sitting. Prominent among these men was Heurteloup who, having recognized that angular fragments made by his percussor "often caused grave accidents, wished to make it possible to extract them without danger." He experimented to that end for a number of years with a spoon lithotribe, which he had invented in 1832, and published in 1846 the result of his labors in a work bearing the title of "Lithotripsie sans fragments, au moyen de deux procédés de l'extraction immédiate ou de la pulvérisation immédiate des pierres vésicales par les voies naturelles." In his memoir of 1832, on the destruction of vesical stones by percussion, he says: "Lithotripsy is the art of crushing stones in the human bladder, in order that the powder and fragments may be expelled with the urine, or that their exit may be provoked by artificial means." To these artificial means he gave the name of lithocœnosis, which signifies evacuation of the stone, from *lithos*, stone, *χενωσις*, evacuation. In this same work he cites Meyriex as having been the first to attempt to make an instrument capable of reducing a stone entirely to powder, but says that this was without success. He also speaks of Tanchou's unsuccessful effort in the same direction, and of that of Vidal and of Amussat. These instruments were designed to grind or rasp the stone from the surface. Our countryman, Dr. E. M. Moore, has for many years been laboring to perfect an instrument designed to reduce vesical stones of considerable size to powder by attacking the surface. The object of all these procedures was to reduce lithotripsy to one sitting, but of half an hour or even much more, and it is very evident that each of these inventors was aware that the bladder containing a stone was often capable of tolerating for a considerable time the presence of instruments; but this tolerance of instruments had been fully demonstrated from the very beginning of the life of lithotripsy. The first operation of Civiale (1824), gave evidence of the greatest tolerance of the bladder to instruments and to angular fragments. This operation required four sittings; two of twenty minutes each, one of thirty-five minutes, and a fourth short sitting whose precise time is not stated. After each of the first three sittings the patient had fever, but suffered

no other serious complication; the treatment having lasted one month. Civiale naively says that, this being his first trial, he had not determined the length that could be given to each sitting. He afterwards, in many cases, shortened the sittings to ten, eight, five, and later, even to three minutes.

Heurteloup labored hard, but in vain, to generalize his operation of lithococosis. No such operations can, or ever will be, generalized, for the exceptional cases will too often be more numerous than those which come within the rule. However, this operation of Heurteloup's with the spoon lithotribe is too good to have been set aside. With slight modifications I believe it can now be applied to a large class of cases. This very ingenious surgeon says, in his work on lithotripsy without fragments, that he has succeeded at one sitting of less than twenty-five minutes in extracting the entire detritus of a stone thirteen centimetres in circumference, weighing twenty-eight grammes; and that though, to accomplish this, he was obliged to introduce the instrument many times, the patient bore the operation well. He further says that larger stones have required two such sittings and sometimes more. In the work in question, he gives a summary of one hundred and twenty-four cases of stone treated by rapid lithotripsy with immediate extraction of the detritus, and I here reproduce the figures. Of these 124 patients, 69 required one sitting; 28 two sittings; 17 three sittings; 5, four sittings; 4, five sittings; and 1 six sittings.

With the spoon lithotribe, and with the aid of an anæsthetic, I believe it possible, in half an hour, to extract the greater part, if not the whole, of the detritus of a calculus one inch in mean diameter. Very recently I felt justified in trying what I could do with a flat-bladed instrument, as I had no spoon lithotribe. Accordingly, on the 3d of October, 1879, I operated, somewhat after Heurteloup's plan, upon a patient sixty-one years of age, and here give the result. The man had, for two years, been under treatment for cystitis and was finally brought to me by a student of medicine. In ten minutes, after five introductions of the flat-bladed lithotribe, I had extracted thirty-two grains of the detritus of a stone five-eighths of an inch broad, half an inch thick, and one inch long. No anæsthetic was used, and the operation was well borne. The patient, who before had always been able to empty his bladder, did not suffer a single bad symptom, except that the sitting of ten minutes had caused enough shock to the bladder, and so disturbed its innervation, as to give rise to temporary paralysis of its muscular coat. I had foreseen this, and directed that he be catheterized at regular intervals. A few hours after the operation he passed a couple of ounces of urine, but this was evidently by the aid of his abdominal muscles and not by vesical contraction. The urine was drawn off four times each twenty-four hours. At the end of the third day he could urinate better, but was not able to empty his bladder. On the fifth day he emptied the bladder spontaneously. On the seventh day I crushed a remaining fragment three-eighths of an inch in diameter. He had passed, partly through the catheter, partly spontaneously, twenty-five grains of well pulverized detritus, and the detritus resulting from the last fragment weighed six grains. The total amount of detritus obtained was sixty-three grains.

I have known sittings of two minutes, in elderly men, to produce this paralysis, and now make it a rule to catheterize such patients every few hours after each sitting, even if they soon urinate spontaneously, and do this to prevent over-distention of the bladder,

which is so apt to cause atony. This precaution should always be taken after prolonged sittings, especially when aspiration of the fragments has been made; for this must surely cause more shock than simple lithotripsy.

ASPIRATION OF GRAVELLY MATTER FROM THE BLADDER, AND OF DETRITUS AFTER LITHOTRIPSY.

Repeated introductions of the scoop lithotribe which was brought out full of detritus were the only means that Heurteloup employed in his operation of lithococosis; he says nothing of aspiration, though Cornay, of Rochefort, had in 1845 published his essay, "De la lithérétique ou extraction des concrétions urinaires," in which are figured several aspirators and large catheters, straight and curved, some of them open at the vesical extremity, some with lateral eyes, others with a single large eye on the convex or on the concave portion of the curved instruments, always within a fourth of an inch of the extremity. Some of these catheters are similar to those at present in use for the aspiration of detritus after lithotripsy. Cornay attempted to apply his methods of aspiration to lithotripsy, but was not successful. It might be urged that aspiration as applied to the extraction of small vesical concretions was known in Europe more than a hundred years ago, that Sanctorius used a syringe for making aspiration of the contents of the bladder, that aspiration of vesical calculi was centuries ago employed by the Egyptians and Arabs; nevertheless, the man who really deserves the credit for suggesting its use in combination with lithotripsy is Joseph Emile Cornay of Rochefort. One year after Cornay's publication, Sir Phillip Crampton's aspirating bottle for extracting calculous detritus became known. Later, Mercier, of Paris, used for the same purpose an India-rubber balloon, with thick walls, at one end of which is a short glass cylinder, the recipient for calculous detritus, and at the other the necessary fittings for the distal end of a large catheter. I have in my possession the original instrument made more than twenty years ago by Charrière. This elastic balloon is described and figured by Mercier in his work, "Traitement préservatif et curatif des sédiments de la gravelle, de la pierre," etc., Paris, 1872, p. 373. After Mercier came Clover, whose apparatus was modified by Robert & Colin, and after Clover, Bigelow of Boston, who has given us an excellent aspirating elastic bag or balloon, which is constructed on a plan similar to that of Mercier. With Bigelow's apparatus more has been accomplished than with any of the others.

For the evacuation of calculous detritus Dr. Bigelow seems to prefer straight catheters. Rectilinear catheterism here, without doubt, has its advantages, but it is, in many instances, very objectionable, and the Doctor tacitly acknowledges this by also employing curved catheters, whose incurvation is not, however well adapted to certain cases complicated with urethro-vesical valves. The eye in these curved instruments is near the point, so that the detritus has to follow the curve, a defect which, for aspiration, renders them inferior to the straight tubes. On this account I have had catheters made by Tiemann & Co. which combine Mercier's rectangular catheter with Bigelow's large-eyed straight tube. In other words, I have added the beak of Mercier's catheter, slightly modified, to the straight tube of Bigelow, and think I have thus obtained a better instrument than either. The form of an ordinary lithotribe's beak may be given to the vesical end of this catheter.

These various contrivances have caused surgeons to

think more about the possibilities of lithotripsy, and have induced many to attempt the operation with their aid in cases where, without them, lithotripsy would have been absolutely contra-indicated. While I think very well of the combination of aspiration with lithotripsy, with the improved aspirators, I believe that it can never supersede simple lithotripsy, lithotomy, or perineal lithotomy, which three operations will be in use as long as men have stones in their bladders. The indications and contra-indications of these various operations seem to me perfectly clear.

A few more words there are which I feel bound to say before dismissing this subject. *The combination of aspiration with lithotripsy is a more difficult and delicate operation than simple lithotripsy, and should never be undertaken except by a good lithotriptist. It is as safe in good hands as it is dangerous when improperly performed. Any surgeon who is not already an experienced lithotriptist and undertakes this operation is guilty of a great wrong.* I have uttered these expressions because some surgeons seem to have thought that anaesthesia and aspiration made the operation easy, and the consequence has been that death has resulted soon after the operation, and from the operation badly done.

THE TREATMENT OF HERNIA BY INJECTION.

By JOSEPH H. WARREN, M.D.,

BOSTON, MASS.

This article was prepared for the Suffolk District Medical Society, but, owing to a lack of time, was not read at the last meeting on September 27th. As a month would elapse before another meeting, and as much interest is shown by the profession, I send this paper, imperfect as it is, and without those comments which would have accompanied the reading, having prepared another paper for the next meeting. My experimental, and as yet incomplete instrument was shown at the meeting, and caused no little interest.

The new and perfected instrument will be made by George Tiemann & Co., of New York City, and will be engraved, and with a minute description be furnished for publication as soon as completed. Allow me to add that if the profession will be a little indulgent, I will give all the information that I can concerning the operation as soon as possible.

I desire to correct the statement in THE MEDICAL RECORD of July 26th, in that rather laudatory article of myself, which says that I induced Dr. Heaton to give his operation to the world during his last illness. It should say that I advised and urged him to do so a number of years before the publication of the work on hernia. That which I have done in the matter will be more highly appreciated when it is known that a committee of men, whom the profession highly honors, sent by the American Medical Association a number of years ago, failed to induce Dr. Heaton to make known his method of operation.

I began operating for the radical cure of rupture soon after the death of Dr. Heaton.

The first patient was Mr. G—, aged 23, with double direct inguinal hernia. I was assisted by Dr. Wm. Emery, of Boston, who was his physician at the time of the operation. The hernial ring on the right side had become dilated to the extent of about one and a quarter inches in diameter by the protrusion of the hernial sac and intestine. The hernia on this side

had existed for over two years, and the tumor formed by the hernial protrusion was about the size of a goose-egg. The hernia upon the left side had existed for about a year and a half, was about one inch in diameter while the hernial protrusion was about one-half the size of the one on the right side. These hernie being at times very painful, and almost impossible to be retained with the ordinary truss during the patient's daily labor, it was thought best to perform the Heatonian operation for hernia, which was done in the following manner. With the old instrument of Dr. Heaton, I injected on the right side about twenty minims of the fluid extract of quercus alba, which had been evaporated to the consistency of glycerine, and united with an eighth of a grain of morphine; on the left side about fifteen drops were injected.

In about six hours after the injection the patient began to grow feverish and restless; pulse running to about ninety, temperature to about one hundred. This condition continued for about three days, when it began gradually to subside. The urine was passed naturally, and a natural passage of the bowels took place on the sixth day. There was some swelling and redness over the hernial ring, extending up over the abdomen obliquely to the crest of the ilium. Dr. Emery attended the case, I seeing the patient occasionally. He administered one-eighth of a grain of morphine at bedtime to secure rest, and cold water was constantly applied over the seat of operation by means of a compress. A rapid and successful recovery took place, with a perfect cure of the ruptures, and on the twenty-third day of July the patient came to my office, when a temporary truss was ordered. This he was to wear for several months until we should conclude that the tissues had gained sufficient strength for him to dispense with it.

It will be seen from the nature of the case that I here felt obliged to use a much larger quantity of the extract of quercus alba than is recommended by the late Dr. Heaton in his work on the cure of rupture. The instrument too, with which he performed his operations, I found very much worn from constant use in his practice for the last thirty years, and very unfit for the purpose for which it was designed, since great manipulation was required to exclude the air from the barrel of the syringe, because of the loose and worn packing. The needle was pierced for the exit of the fluid with two small holes about one-fourth of an inch from its point. In order, therefore, to apply the mixture thoroughly to all the circumference of the ring, internal and external, it was necessary to twist the needle around during the injection. The fact is, however, that this method of operating caused a very unequal distribution of the fluids upon the parts, and much pain and needless suffering to the patient.

I examined also the needle devised by Dr. Davenport, and found his likewise had but two openings, with what I consider a very dangerous point, it being lancet-shaped, and liable to pierce the pubic and branches of the epigastric arteries, together with other vessels. It thus had not even the merits of Dr. Heaton's old needle, which was in shape not unlike a bradawl at its point, and which, because not very sharp, easily glanced by any vessels it might meet in its passage through the integuments.

Accordingly, in my next case I had a needle made for me and pierced with four holes, the first two much nearer the point of the needle than in the old instrument. This new needle, I found, worked very much better, distributing the fluid more equally upon the internal and external ring, together with less turning

of the needle in the integuments, and consequently much less pain in the operation. With this needle, as I had improved it, I continued to perform several operations with much better success than with the needle devised by Dr. Heaton. Still, when I came to operate for a very large double inguinal hernia, one direct and the other oblique, the distance through the integuments being greatly increased by adipose deposit, I found there was still a great amount of pain which I thought unnecessary, produced by the instrument—since, being rather blunt at the point, it therefore met with considerable resistance in penetration.

When I came to make a second injection, which was necessary on the left side of this hernia, since the first injection did not succeed in causing the adventitious tissue to be thrown out so as to fully close the ring, I found much greater resistance in the integuments than before, they having become more firmly consolidated from the effect of the oak bark. The operation thus caused considerable pain, although no more than most patients could endure without etherization.

I next turned my attention to find some means of penetrating the tissue into the hernial ring with less pain, and for this purpose devised a new instrument which I now take pleasure in showing you. It consists, as will be seen, of a glass barrel inclosed in silver, through whose fenestrated openings the fluid can be seen and the presence of air-bubbles detected. The number of minims is also plainly indicated on the engraved glass barrel, so that we can measure the exact number of drops injected in any given operation. It has two semicircular handles on the lower end for holding the instrument conveniently and firm during the operation.

If we next examine the needle or beak, we shall see that it is hollow, about one and three-quarter inches long, and that throughout its whole length it partakes of a spiral twist, so that it will, of necessity, revolve as it enters the tissue, and by such revolving penetrate the skin and other integuments much more readily than is possible with a straight, bluntly-pointed instrument. We can readily illustrate this by passing the improved needle through a piece of parchment, and then by performing a similar operation with a straight needle pointed like a brad-awl.

The ease with which the first needle penetrates compared with the resistance which the other meets, proves conclusively that the former instrument must do its work with much less pain than the latter. The secret of this is, that with the straight needle we get constant friction and bearing on the entire length of the needle during the whole operation, whereas with the spiral form of the needle the friction and pressure are on but a small portion of the body of the instrument at any one time, and are thus reduced to the minimum.

Then, again, it is to be observed that the needle, instead of being round, is of a flat, oval shape, and makes a wound of the same form. In this way there is a more ready coaptation of the wounded tissue than would be possible with a round puncture. The needle is pierced with ten openings upon its sides, which causes a more free and equal distribution of the fluid ejected. The difference between this and the hypodermic needle which I shall speak of later on, is that instead of the direct terminal flow of the fluid, we have it spread at right angles to the needle, and therefore gain a better distribution upon the hernial rings, internal and external, at the same time avoiding the application of the fluid to the peritoneum, which we wish to irritate as little as possible.

With the hypodermic syringe, however, the principal flow of the fluid would be upon the peritoneum, and not upon the parts intended to receive it, thus making the operation, in view of the small amount of fluid recommended, of limited and doubtful success. If we examine the attachment of this needle to the barrel of the syringe, we shall see, moreover, that the needle is held in place by a coupling and collar which allows it to revolve while on its passage through the integuments. The head of the needle within this collar is rounded something like the smaller end of an egg and on its bearings is in contact with a diamond or other hard stone which is concaved to fit accurately the convexity of the needle. In this way we avoid almost entirely the friction which would, if metal met metal, prevent the free revolution of the needle; and at the same time we render the joint sufficiently tight to prevent all leakage of the fluid as it passes from the chamber of the instrument into the needle. A bulbar opening at lower part of this chamber, opening and closing by simply pressing on a lever, allows as much or little fluid to escape, and just when you wish it to, at any stage of the operation.

In addition to this it should be stated that in my method of performing the operation, instead of applying the fluid to the internal hernial ring first, as in Dr. Heaton's operation, I reverse the process and do this last; for as soon as my needle has penetrated the tissues, I immediately begin to eject the fluid upon the external ring and its surrounding parts, and so continue until I reach the internal ring. After sufficiently bathing the latter with the fluid I withdraw the instrument, still continuing to eject.

In performing in this manner we complete the operation in one-half the time employed by Dr. Heaton, and, comparatively speaking, with an absence of pain. At the same time we entirely avoid the sweeping motion of the needle described in Dr. Heaton's treatise, a process which I consider very much endangers the wounding or irritation of the muscular fibres and blood-vessels composing the rings.

Furthermore, the tissues being less likely to be scratched or irritated with my needle than with his, there is much less tendency to the formation of abscesses from such irritation than in the old operation.

I find, too, that the extract of oak bark employed by Dr. Heaton is not well held in solution, being liable to much sediment, the powder forming granulations which do not readily pass through the syringe, and which, if ejected, form a considerable irritation, and therefore a great tendency to abscesses. A better and safer formula is to evaporate the fluid extract of oak to about the consistency of glycerine, add sufficient absolute alcohol to reduce it about one-half, and then add about one-half a drachm of sulphuric ether to the half ounce of fluid. To this mixture I also add about two grains of sulphate of morphia, thus making one of the most perfect injecting fluids that I have thus far been able by numerous experiments to devise, combining the astringent effect of Dr. Heaton's extract of quercus alba, together with that of the German method of using alcohol alone, and producing the most favorable results in this operation of injecting the hernial rings for the radical cure.

The use of an ordinary hypodermic syringe would be, I consider, an operation attended with much danger, not only from the liability of penetrating a portion of the pubic and epigastric arteries, but also because the instrument would be a poor and feeble one for thorough and successful operations on hernia, since it is well known that the needle has to act in

some degree as a staff and guide in slightly lifting up, as it were, the integuments, which are often thick and supplemented by excessive adipose tissue.

Although it is high time that this operation should be better understood, still a thorough comprehension will neither lessen our great esteem for the more formal surgical operation for strangulated hernia, as now performed by all modern surgeons, nor will it be less essential for all practical surgeons thoroughly to understand this latter operation.

So long, however, as thousands upon thousands are ruptured with reducible herniæ, which have heretofore required all the ingenuity of mechanical art to support and retain within the abdominal cavity by bands of iron and steel, elastic fabrics, bone and ivory, thereby endangering life by their liability to become strangulated, and often abruptly terminating existence by the strangulated intestines becoming spatulous and gangrenous, before relief can be obtained by the surgeon's knife or the more gentle operation of taxis; so long as this is the case, the discovery of a permanent cure seems a most wonderful blessing for mankind.

At a future time I hope to be able to describe more in detail the method of radical cure, as I perform it, and illustrate it by such cases worthy of peculiar mention as may come under my observation, as well as the number I have operated on.

Should I ever be disappointed in the success of this operation for the relief and cure of rupture, I should be the first to acknowledge it.

Allow me to add, I know of no operation in the annals of surgery that requires a more delicate touch, and finer manipulation in all of its details, or a more steady and firmer hand in the operator, not even excepting the fine and graceful operation of cataract on the eye. What operation demands more care than passing a sharp-pointed instrument through the living tissue into the hernial ring, among numerous tissues, vessels, nerves, and surrounded by the peritoneal membrane? I know of no operation more simple and painless, or that brings forth such rich results in relief, comfort, and almost certain cure in almost every case when performed by a skilful operator, than this one for the radical cure of rupture. But when awkwardly and indifferently performed by one deficient in the anatomical and surgical knowledge proper for the undertaking of the operation, I know of no operation so fraught with danger to human life, and one so barren in results, and therefore disappointing to both physician and patient.

Finally, I wish to add a word of caution and advice to those who may have to do with this operation. Should the patient get up too soon after being operated upon, or make any undue exercise or exertions before the parts have acquired sufficient union, consolidation, and firmness, they will very readily become separated, and of course let the hernia escape again; or, should there be union in the parts sufficient even to retain the hernia within the abdominal rings, yet a secondary swelling may again appear in the track of the first swelling and inflammation which usually attends the primary operation.

This secondary swelling, more particularly if it follows after we have made two or three injections, which are often found necessary to fully close the hernial rings, will appear in any form of inguinal hernia very prominent over the seat of the injected parts, not unlike an inverted common saucer in size and appearance, extending along the oblique to the crest of the ilium, and will assume a dark maroon color. If we

now examine it, it will appear to the touch as though fluid or pus were present.

This is not, however, the case; but it is only a slight effusion and exudation of plasmatic serum, together with some mingling with the discoloration produced by the extract of oak injected. If now we cut freely down, exposing these parts to view, we see that the tannin in the mixture injected has united with the exudation, causing the appearance of the tannate of albumen. This will show itself by the striated, shroudy, and granulated substance resembling dry blood when moistened again. If we should now constantly apply compresses of cold water and allow the patient to remain in bed, on his back, this redness and swelling will generally, in the course of two weeks, entirely disappear.

Such cases, when fully over all inflammatory attacks, will be found to be stronger in the hernial rings than those which had only the primary inflammation following the injection, because this secondary inflammation more fully unites the parts inflamed by thickening an additional deposit of organized lymph over the seat of the operation. But we should not be misled by this inflammation and proceed at once to open this large swelling, as we thereby very greatly endanger the result of the primary operation for the relief of the rupture, and put the patient's life in great and needless danger.

We should therefore patiently wait, and after a sufficient time, it will, if it be an abscess, converge, in the course of ten or twelve days, to about the size of a Sichel pear, and something like it in shape and appearance. Then, and not until then, we should proceed to open the swelling, and even then we should first be able to feel the fluctuation of the pus through the thinned walls of the abscess. And if still in doubt, from our diagnosis, whether it be an abscess or not, we should, before opening, pass into the swelling one of the finest needles of the aspirator.

Cold water is the best dressing, and all through the treatment, from the very beginning to the perfect recovery to the normal condition of the inflamed parts, neither lotions nor ointments are required.

Now, sometimes when we discharge a patient after this operation, he is commended to wear a truss or bandage, not to lift or jump either from the cars or any other height, and to be very careful about any violent exercise whatever; all of which he promises to do. But the person so dismissed, cured to all appearances, will possibly feel so mighty and proud in his recovery that, although he may for a time follow the instructions, he will some fine morning cough, perhaps, and force the abdominal parts down in order to see how strong he is in this region; or taking a peculiar delight now in examining what previous to the operation was so repulsive, he will try to lift a heavy weight, pull a hand-cart if he takes a notion, or see how high he can reach.

From these self-examinations he may feel satisfied that he is perfectly cured, and yet, in the very acts in the time of his unusual exertions, he has started and opened the adhesions formed in the hernial ring, and in the end his state will be nearly as bad as before; for upon the least yielding of these new adhesions the peritoneum and intestines will insinuate themselves through the most minute opening, and act like a wedge in forcing the parts asunder.

Had he been more cautious in following explicit directions, and waited a year or two before making violent exertions, he would never have had to bear a return of his rupture. Should a return of his hernia unfortunately take place, another operation and injection

tion will generally effect even a firmer closing of the rings than the first operation did, because of a decidedly greater condensation and stronger cohesion of the parts treated. But I am assured that he never again, in his joy, will experiment to see how perfectly he is cured.

Sometimes, after the hernial rings are closed, as Dr. Heaton says in his work, and as I myself have seen, portions of the hernial sac, particularly in cases of long standing, are fastened down in the folds of the rings and surrounding parts, after the operation for radical cure has been successfully applied, and this may lead the patient—nay, even the physician, to think that the hernia has not been in reality cured. If, however, as I have already said, the rupture remains closed for a year or so, the cure may be looked upon as certainly a permanent one.

Suppose, however, that this hernial sac can be passed readily through the hernial rings; then a very slight amount of the injection will close the parts efficiently, leaving the patient much strengthened by the operation.

I wish to call attention again, and especially to the fact that although this operation is generally successful upon its first performance, yet it has sometimes to be repeated several times before we get a full and strong occlusion of the rings, particularly in hernie of large and long standing. If, after we have once operated and have succeeded in partly closing the opening, we find we have not done it so as fully to effect a permanent cure, we must, after the lapse of eight or ten days, repeat the operation, and continue so to do until we have entirely closed the parts beyond danger of opening. Thus, by perseverance, and thus only, we shall in the end be delighted and rewarded by the perfect cure of almost every case we undertake.

Even after the patient has returned to his usual occupations, and has seemed, both to himself and the operator, cured, upon the slightest indication of the return of his troubles he should at once present himself for examination, and, if necessary, another operation. Indeed, not only in this operation, but in all others in surgery that may be presented to me for treatment, I could not positively, and under all circumstances, warrant a permanent cure any more than if I performed ovariectomy or the amputation of a limb, for it is well known that from some unforeseen circumstance in the operation, or in the conduct of the patient submitted, success may not always and with certainty follow a good and legitimate attempt at relief.

THREE CASES OF GLAUCOMA.

By DAVID WEBSTER, M.D.,

NEW YORK.

WELLS says: "The persons attacked by glaucoma are mostly beyond forty-five or fifty years of age."

Carter says: "The patient is commonly past the middle period of life."

Schweigger says: "It occurs very rarely before the thirtieth year."

Charles Higgins says: "It, as a rule, attacks persons beyond middle age."

Spencer Watson says: "There are recorded cases of glaucoma occurring even in infancy." But out of forty-six cases reported by him the youngest patient with uncomplicated glaucoma was twenty-eight years of age.

The extreme rarity, then, of glaucoma in children

is my excuse for publishing Case I. It is the only case of uncomplicated glaucoma in childhood, or even in youth, that I have ever met with.

Judging from what the books say, cases of hydrophthalmus, or kerato-globus, with glaucoma, occurring in the young, are not quite so uncommon.

In the cases that I have seen, however, there has usually been so much opacity of the cornea as to obscure the fundus, prevent an inspection of the optic disc, and reduce the vision to little more than perception of light. In such cases, of course, the glaucomatous condition can be determined only by the hardness of the eyeball, and, perhaps, the dilatation of the pupil.

In the case here reported the cupping of the disk could be so distinctly seen that its depth was measured. The amount of vision retained by the eye ($\frac{2}{100}$) was also considerable.

Case III. is the only case I have seen where strychnine injections improved the sight of an eye affected with glaucoma, and I have seen the remedy tried in several cases. I still have my doubts whether the improvement in vision was not due as much to the cutting off of the patient's tobacco and beer, and thus avoiding their poisonous influence upon his nervous system, as to any curative effect it exercised upon the glaucoma.

CASE I.—*Glaucoma Simpler in a Child Ten Years of Age.*

Ida S—, æt. 10, was brought by her father to consult Dr. C. R. Agnew on April 5, 1876. The following history was noted:

The child saw perfectly well up to four months ago, and could read ordinary print up to one month ago, since which she became rapidly blind in both eyes.

The first thing that called attention to her eyes was that on attempting to fix she looked cross-eyed. Her parents, on observing this deviation of her optical axes, took her to their family physician, who gave her medicine and ordered a solution of atropine to be dropped into her eyes daily. This treatment was continued for about two weeks.

She has never complained of pain in or about her eyes, and has not suffered from headaches, but has lately complained of dizziness.

No eye-drops have been used in either eye for more than three weeks, and yet both pupils are widely dilated.

The tension is very much increased in both eyes, but more markedly so in the left.

Neither eye retains preception of light, the patient being unable to appreciate the light from an argand burner when concentrated upon the pupil by means of a two-inch lens.

Ophthalmoscopic examination shows both eyes to be emmetropic. The media are perfectly transparent. The right optic disk is excavated to a depth of 1.8 mm. ($-\frac{1}{8}$); the left, 2.14 mm. ($-\frac{1}{4}$). There is a narrow ring of choroidal atrophy around the margin of the excavation.

There is marked pulsation of the retinal arteries in both eyes. In the left the arteries seem to spring forward from the bottom of the cup with each beat of the heart.

A discouraging prognosis was given, and iridectomy upon both eyes was advised, but declined.

CASE II.—*Glaucoma with Kerato-globus.*

Mary L—, æt. 10, came under observation Feb. 27, 1878. Her parents stated that she was born with the right eye larger than the left, but in so far as they

were able to judge, she saw as well with it as with the left until she was eight years of age. The child says she never could see to read with the right eye. The mother has lately observed frequent involuntary rolling of both eyes, with other symptoms of chorea, as twitching of the face and jerking up of the shoulders.

The right eye is from one-third to one-fourth larger than the left, and the sclera is so thinned that the dark choroid shines through it, giving the whole "white of the eye" a bluish appearance. The cornea seems about a third larger than the cornea of the other eye, and the anterior chamber correspondingly deep. Tension normal.

R. V. = $\frac{20}{20}$, without a glass, but raised to $\frac{20}{30}$ with $-\frac{1}{2}$. L. V. = $\frac{20}{20}$; Hm. $\frac{1}{100}$.

Ophthalmoscopic examination of the buphthalmic eye shows some diffuse opacity of the cornea. The fundus is best seen through $-\frac{1}{4}$, and is streaked and mottled with pigment. There is cupping of the entire optic disc to a depth of about 0.91 mm. ($-\frac{1}{2}$). There is no visible pulsation of the retinal vessels, and no very marked ring of atrophy about the disk.

The field of vision is contracted to about half its normal size, and rather more upon the nasal side than in other directions.

Non-interference was advised.

CASE III.—*Glaucoma Simplex, with old Corneal Opacities of both Eyes, benefited by Strychnine Injections.*

A. K.—, *et.* 41, German, lager beer saloon-keeper, came to see me at the Manhattan Eye and Ear Hospital on March 19, 1877. He said that his eyesight had been very poor for many years, but had lately been growing much worse. He has had no pain, photopsie, or chromopsie. He has been in the habit, for years, of smoking and chewing tobacco, and of drinking lager beer excessively.

R. V. $\frac{20}{20}$, L. V. $\frac{10}{20}$; neither improved by glasses. Both visual fields concentrically contracted, left more so. Tension slightly increased in both eyes, and pupils of both eyes sluggish.

Examination with the ophthalmoscope and with lenses showed the existence, in both eyes, of such corneal opacities as usually follow phlyctenular keratitis, and complete excavation of both optic disks.

The depth of the cupping could not be accurately measured by reason of the corneal opacities, but all who examined the eyes agreed that the excavation was unquestionably glaucomatous.

Mr. K. was directed to stop the use of tobacco and beer, and was placed upon hypodermic injections of nitrate of strychnia, commencing with gr. $\frac{1}{10}$ and adding gr. $\frac{1}{10}$ to the dose daily.

April 10th.—R. V. $\frac{20}{20}$, L. V. $\frac{10}{20}$.

April 14th.—R. V. $\frac{20}{20}$, L. V. $\frac{20}{20}$.

May 1st.—Mr. K.'s vision remains as at last date. He can read his German newspaper, and declines further treatment.

THE METRIC SYSTEM IN ENGLAND.—Dr. E. Seguin read an address on the subject of the metric system at the recent meeting of the British Medical Association in Cork. Subsequently, on motion of Mr. Ernest Hart, editor of the *British Medical Journal*, a committee was appointed to report on the means of introducing the metric system in medicine in Great Britain. Among the members of the committee are Dr. Lauder Brunton, Dr. Quain, and Mr. Hart.—*Medical and Surg. Reporter.*

Progress of Medical Science.

TREATMENT OF WHITE SWELLING BY INJECTIONS OF SULPHATE OF ZINC.—M. Léon Le Fort described to the *Société de Chirurgie* a new method of treating white swelling, which he had tried on a patient who had suffered from fungous disease of the knee-joint for four years. All the classical treatments had failed to give relief, and on May 12th, M. Le Fort injected into the cavity of the joint a ten per cent. solution of sulphate of zinc, one quarter alcohol being added. No inflammatory reaction followed the injection, with the exception of a slight amount of induration at the point of puncture. This was repeated once a week, but before injecting the caustic liquid, he always removed with the aspirator the pus contained in the joint. This pus never exceeded thirty grammes in quantity, and diminished gradually with each succeeding puncture. The patient is now in good condition, his knee has diminished in size, and it has become possible to move the articulation. The patient has not completely recovered, but as he is charmed with the progress already made and wishes to leave the hospital, M. Le Fort desired to present him before the adjournment of the society.—*Moniteur de la Polyclinique*, August 17, 1879.

THE ACTION OF THE DIGESTIVE FERMENTS EMPLOYED IN THE TREATMENT OF DYSPEPSIA.—At a recent meeting of the *Académie de Médecine*, M. Vulpian laid before the society the results of his investigations into the action of pepsin, pancreatin, and diastase. The different preparations of pepsin were found to be of very variable strength, many of them so feeble as to be absolutely useless as remedial agents. The addition of alcohol to an acidified solution of pepsin or to natural gastric juice, retards digestion when the proportion of alcohol in the solution exceeds that of claret or burgundy wine. From this the conclusion is drawn that wines and elixirs of pepsin should not be used. Some of the elixirs examined contained but very small proportions of the principle, the rest having been precipitated by the alcohol during the manufacture. Pancreatin and diastase, when mixed with artificial or natural gastric juice, have not as energetic an action on starchy matters as when pure water is used for their solution. M. Mourrut, who continued the investigations under the direction of M. Vulpian, found that the effect of acid was to retard the action of diastase, and to destroy that of pancreatin. The effect of alcohol, he found, was to retard the action of all the ferments, an effect, perhaps, most marked in the case of pepsin.—*Gazette Médicale de Paris*, August 16, 1879.

LYMPHADENOMA OF THE TESTICLE.—The investigation of this subject is of recent date, Dr. Malassez, in 1874, having been the first to call attention to the distinction of this disease from sarcoma. Five cases have been collected by Drs. Monod and Terrillon, who had an opportunity of examining the specimen taken from the last. In their very interesting report on these cases they advance the following conclusions:

1. Lymphadenoma of the testicle is a tissue of new formation, having a structure similar to that of the lymphatic glands.
2. It constitutes an anatomically distinct variety of sarcocele, the diagnosis of which is not impossible during life.
3. It seems to confine itself to the gland itself, sparing the epididymis.

4. The whole gland is affected from the first. The lesions appear to begin in the intertubular tissue, and to attack secondarily the walls of the seminal tubes, which gradually disappear as the neoplasm increases.

5. Lymphadenoma of the testicle may affect, at the same time or successively, both testicles—a characteristic of this variety of neoplasm.

6. The infection of the general system is early and rapid. The disease is frequently found in the viscera, in the bones, and in the cutaneous and subcutaneous tissues at great distances from the original focus.

This character, like the preceding, is of great help in the diagnosis:

7. This systemic infection can exist for a comparatively long period, without inducing any appreciable cachexia.

8. Lymphadenoma of the testicle is not apparently accompanied by leukemia.

9. The prognosis is fatal, and up to this time surgical intervention has been of no avail.—*Archives Générales de Médecine*, July, 1879.

ON THE THERAPEUTIC USES OF THE BENZOATE OF SODA.—Buchholtz discovered that the benzoate of soda possesses in a high degree the power of preventing the development of bacteria in putrescible fluids. Brown found that a previous hypodermic injection of the drug will prevent, to a certain extent, the development of diphtheria from inoculation in an animal. Dr. Schüller, of Greifswald, used it as an antiseptic dressing, but did not find that it possessed any advantages over carbolic or salicylic acid. Given internally, however, he found it very beneficial in several cases of extensive phlegmonous processes in the hand and forearm, and of erysipelas, and in one case of diphtheritic inflammation of the bladder. In all of these cases the fever disappeared entirely, and the local symptoms improved, after from 10 to 20 grammes had been taken. The effect was particularly striking in a case of violent traumatic erysipelas with chill and high fever, in which 25 grammes were taken within 24 hours. The fever began to sink after a few doses had been administered. The remedy also proved useful in some cases of scrofulous articular affections with simultaneous catarrh of the pulmonary apices and persistent eczema. Schüller's formula of administration was: benzoate of soda, 10 grammes; syrup, 20 grammes; water, 200 grammes (ʒiʒss.—ʒv.—ʒvʒss.). Dose, a tablespoonful four or five times daily, when its use was continued for a long time, and every hour in acute febrile affections.

Prof. Klebs believes that the drug is absorbed very slowly by the intestines when fever is present, and hence recommends its direct injection into the blood. Experimentally it seems to be demonstrated that immense quantities can be injected into the blood without danger; as much as 5 grammes would have to be injected in the case of a man of ordinary size, to prevent the development of bacteria in the blood. The only danger to be feared would be paralysis of the heart, an effect which would be due to the soda rather than to the benzoic acid. Klebs suggests that this danger might be avoided by the use of the less soluble *benzoate of magnesia*. This salt may also be given internally in powder or pills in place of the benzoate of soda, when the latter causes nausea. The *benzoate of lithia* is said to be more soluble than the magnesia salt, and like it to have no action on the pneumogastrie.

Letzerich gave the benzoate of soda in eight cases of severe diphtheria in children, and states that no other remedy has produced in his hands such rapid and

lasting effects. The temperature usually fell in from 24 to 36 hours. Only one of the patients died—a badly nourished child, who had just recovered from an attack of croup. Besides the internal administration of the drug, it was employed locally by insufflation or gargles. Hoffman, of Berlin, treated 12 cases of diphtheria with the drug; all of them recovered. He believes that the medicine essentially shortened the course of the disease. On the other hand, Widerhofer, of Vienna, treated 17 cases of diphtheria in children with the benzoate of soda, and lost eight of the patients. He does not regard it as a reliable remedy in this disease.

Letzerich also recommends the benzoate of soda in gastric catarrh, particularly in infants, and in this he is seconded by Kapuscinski, of Posen, who administered it in 63 cases of gastro-intestinal catarrh in children under five years of age, with the most striking results. The vomiting was controlled very rapidly, but the drug had no power over the diarrhoea, which yielded, however, to bismuth and soda after the vomiting ceased. He gave one or two teaspoonfuls of a 5 per cent. solution of the salt every two hours. Finally the benzoate of soda has been given with good effects in two cases of morbus Brightii, one of which had already presented uræmic symptoms. Five grammes of the salt were given three times a day, and under this treatment the albumen in the urine rapidly diminished, and soon only traces of it were left.—*Allg. med. Cent.-Zeit.*, July, 16, 1879; *Deutsche med. Wochen.*, August 9, 1879, and *Schmidt's Jahrbücher*, 1879, No. 5.

LOCAL TREATMENT OF PALMAR SYPHILIDES.—Those syphilitic affections of the hand, described as *psoriasis palmaris*, are remarkable for their great rebelliousness to internal treatment. It is necessary that local applications should be combined with the internal administration of remedies. These should consist in frictions with soft-soap, and enveloping the hands in flannels soaked in the same remedy. Under this treatment the epidermis will soften and peel off, and the affected parts may then be painted with tinct. iodine, or touched with nitrate of silver, when the lesions will quickly disappear.—*Journal de Médecine*, August, 1879.

TREATMENT OF THE EPHELIDES OF PREGNANCY BY CHRYSOPHANIC ACID.—Chrysophanic acid has been used with considerable success by Neumann and Braun in those pigmentary patches which appear on the skin during pregnancy. The acid has an irritant action on the skin similar to that of nitrate of silver and other topical remedies, under the influence of which the epithelial and subepithelial layers are destroyed, and the pigmentation disappears and does not return. The irritation excited should only be sufficient to cause the disappearance of the spots, but it is sometimes difficult to limit it to this, owing to the very variable susceptibility of the skin to the action of the acid. The parts should be well washed with soap and water, and the following ointment applied without friction: R.—Acid chrysophanic, 1 grm.; lard, 40 grms. The salve is spread on a rag and applied to the affected part, care being taken not to allow it to spread further than the discolored spot. Ordinarily, friction may be used three or four times at two days' interval, but it is necessary to watch the skin, and if much swelling appear the frictions should be stopped. The application of the ointment is followed by swelling and moderate burning, the parts become red, and then black, then de-quamation takes place and the spots disappear.—*Journal de Médecine*, August, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

W.M. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 18, 1879.

A NEW MALARIAL GERM.

NEXT to the North Pole it is probable that specific germs have been the most prominent object of recent scientific inquiry. And it has happened that, since the malarial germ is the most common and the least noxious of these hypothetical organisms, there have been especially numerous efforts to capture it. We have the pleasure of chronicling the last, and we believe the seventh announcement of its authentic discovery. It has been found amongst the Pontine marshes. It was here that Balestra several years ago found a species of alga, which appeared to be the poison. Here, also, M. Lanzi and G. Terrigi, in 1875, found certain dark-colored granules developing in decomposing slime, and identical, as it seemed, with the melanine granules in malarial spleens and livers.

The present researches have been made by Professor Klebs and Signor Tommasi-Crudeli, and have been conducted with a scientific precision which makes their claims of success worthy of more attention, perhaps, than those of any of their predecessors. Their method of procedure was as follows:

They gathered from the earth, air, and water of malarious regions infectious solutions, which they proved to be malarial by the peculiar paroxysmal temperature waves and the enlarged spleens which were produced when portions were injected into the subcutaneous cellular tissue of rabbits. They then separated the solid parts of the infecting solutions from the liquid by filtration, generally through plaster-of-Paris. In this way they discovered that the poison was a solid, for the filtrate scarcely ever produced any rise of temperature, while the residue always had the specific effect.

The organisms in this residue, which are thought by the observers to be the true causes of malaria, are minute spores, .35 micromillimetres in diameter, oval in shape, and belong to the genus *vacillus*. The name

given them is *vacillus malarie*. They do not develop in water—indeed, a large quantity renders them inactive—but require free oxygen and substances rich in nitrogen. In the body they develop to the greatest extent in the spleen and medulla, a fact noted as important, since it is here that the most characteristic anatomical changes are found in those suffering from grave malarious fevers. The organism multiplies by transverse fission, thus converting itself into a chain. In the interior of the links spores appear and eventually fill it.

A writer in *The Practitioner*, assuming that either the *vacillus*, or some other vegetable organism, is the cause of malaria, applies to it the observations of Lussana, and thus makes a very complete and, so to speak, rotund hypothesis. Lussana found that some poisons, particularly curare, when taken into the stomach, do not at once enter the general circulation, but pass to the liver, are excreted with the bile, and absorbed by the intestinal vessels again. If the poison is small in amount it may continue this round indefinitely. Now, the *vacillus malarie*, it is thought, lodges in the mouth and pharynx, is swallowed with the saliva, and taken into the portal circulation. If the quantity is great some pass into the general circulation, produce alterations in the quality of the blood, which affect the nerve-centres and cause the ague fit. A few continue in the portal circulation, but soon multiply there and discharge their surplus into the general blood current again. Thus the morbid process goes on.

We have presented these observations and theories somewhat at length, because they have been made with great care, and are endorsed by men whose scientific attainments are unquestionable. The experimenters appear confident that they have demonstrated their point, but the profession will hardly accept their conclusions without a good deal more evidence. We have had the same claims from other observers, and made with equal confidence, though not, it must be confessed, supported by an equal array of facts. But the *vacillus malarie* must be found in some other place than the Pontine Marshes, and we wish to know, also, how it manages to exist on the slopes of the Andes, 6,000 feet or more above the sea, with no swamps anywhere about.

It will be a great triumph for the believers in the germ theory if the observations of Klebs and Tommasi-Crudeli are confirmed, and it will be an advantage to science, in any event, that further experiments, conducted in the same precise methods, are likely to be inaugurated.

THE AMERICAN GYNECOLOGICAL SOCIETY.

We furnish our readers, in this number, a somewhat extended report of the transactions of the American Gynecological Society, at its annual meeting held in Baltimore, September last. Upon the important sub-

ject of intra-uterine medication we are able to give interesting points additional to those already presented in a previous number, and, under the head of puerperal septicæmia, immediately following, are additional considerations bearing upon the same subject. The address by the President, Dr. T. Gaillard Thomas, was not only a highly accomplished production, but one which contained much food for thought. With his position regarding medical literature we are especially pleased, and believe that if a more thorough, impartial, and scrutinizing review, sacrificial if needs be, was given to the volumes which are poured out yearly, a great and lasting good would be accomplished.

A few papers are worthy of special mention because they are upon either new subjects, or upon subjects which have not received the attention which their importance demands.

The paper presented by Dr. A. J. C. Skene, of Brooklyn, contains original observations among a class of patients hitherto unstudied from this special point of view. Only the conclusions reached by Dr. Paul F. Mundé, of this city, in his paper, are given, yet they embrace important points in the diagnosis and treatment of an affection which has not received due consideration in the text-books on diseases of women.

The paper by Dr. Isaac E. Taylor, coming from such a skilled operator, is entitled to careful consideration, and is especially interesting in the light of the recent discussion on the use of the obstetric forceps, held in the London Obstetrical Society, with an abstract of which our readers have been already supplied. To use the forceps in the first stage of a natural labor, merely to assist nature, nothing more, although a doctrine advocated for many years by Dr. Taylor, has not been brought so prominently before the profession as in the present instance.

Dr. J. Taber Johnson, of Washington, read a paper which has a practical bearing upon preventive medicine in a most important department. We fear it will not receive the study to which it is entitled, simply because it strikes so deep at the root of the culpable practice of too many careless practitioners.

A large number of papers were presented which were not read. Those which were read, in general possessed notable value, and the discussions which followed enhanced their worth to a marked extent. Of course there was much dross with the gold exhibited, but unfortunately this is one of the characteristics of all medical societies carried on upon the open plan which of necessity governs the working of all such organizations. The fourth annual meeting of this society, however, was a success, and none of its members or invited guests have reason to regret that it was held in Baltimore, where they were received with open arms, open hearts, and open houses, by the medical profession of the city.

CONSERVATIVE JOURNALISM.

SEVERAL months ago the *Philadelphia Medical and Surgical Reporter*, in discussing the subject of licensed prostitution, took occasion to praise the workings of the British Contagious Diseases Acts; it also complimented very highly the medical press of England for its stand in favor of these laws, and lamented the dullness and conservatism of American medical journals in not advocating the regulation of prostitution in this country, and thus taking equally broad views with their English brethren. Subsequently a special reference was made to **THE MEDICAL RECORD** for its very ridiculous backwardness in this direction.

Now the facts are, as we have shown, that the Contagious Diseases Acts have only a limited and peculiar application. A journal might consistently defend them and yet deny the utility of the general adoption of regulation measures. The fact, therefore, that English medical journals are in favor of these acts, while American journals do not advocate any of the present systems of regulating prostitution, furnishes no evidence that the latter are unenlightened and unprogressive. The melancholy of the *Reporter* over the blindness of its exchanges would seem to be quite illogical.

There are times, however, when an apparent shallowness of reasoning is not so much an evidence of insufficient intellect as of inadequate information; and we are glad to think that this is the case with our esteemed contemporary. We recommend to it a more extensive perusal of the literature of the subjects which it discusses.

Reports of Societies.

THE AMERICAN GYNECOLOGICAL SOCIETY.

Fourth Annual Meeting, held in Baltimore, September 17, 18, and 19, 1879.

WEDNESDAY—SEPTEMBER 17TH—FIRST DAY—MORNING SESSION.

The Society met in the Johns Hopkins University, and was called to order at 9.30 A.M. by the President, DR. T. GAILLARD THOMAS, of New York.

Thirty Fellows responded to the roll-call.

The address of welcome was given by Dr. W. T. HOWARD, of Baltimore.

INVITED GUESTS.

The following gentlemen were elected members by invitation: Dr. W. H. Baker and Dr. W. C. B. Fifield, of Boston; Dr. J. S. D. Cullen, of Richmond, Va.; Dr. W. A. B. Norcom, of Edenton, N. C.; Dr. C. W. Franzoni, of Washington, D. C.; Dr. H. H. Battey, of Rome, Ga.; Dr. N. D. Baker, of Martinsburg, Va.; Dr. Henry Carpenter, of Lancaster, Pa.; Dr. W. Selden, of Norfolk, Va.; and President D. C. Gilman, Dr. J. Carey Thomas, Dr. G. Lane Taneyhill, Prof. G. W. Miltenberger, Prof. Alan P. Smith, Prof. S. S.

Chew, Prof. A. F. Erich, Dr. B. B. Browne, Dr. Thomas H. Buckler, Prof. Christopher Johnston, Dr. J. J. Chisolm, Prof. F. Donaldson, of Baltimore.

PRESIDENT GHLMAN then made a brief allusion to the work of the University, and welcomed the Society in behalf of the two foundations bearing the name of Johns Hopkins.

The first paper was read by DR. JAMES P. WHITE, of Buffalo, N. Y., on the subject of

INTRA-UTERINE MEDICATION,

and in it he passed over pathological conditions and the therapeutics of those conditions, and simply gave some hints regarding the means which had been found available in the proper application of remedies to the mucous membrane of the neck and body of the uterus. Although intra-uterine injections were advised by some, they were rarely resorted to by the experienced practitioner. He spoke of the necessity of enlarging the cervical canal before resorting to this method of treatment. He recommended shallow incisions into the mucous membrane of the neck of the uterus, to facilitate in certain cases the introduction of sponge-tents. If properly made, no harm followed the incisions. After removing the catarrhal discharge from the cervix, he very commonly used the following as a local application:

R.	Iodine.....	3 i.
	Iodide of potassium.....	3 ss.
	Tannin.....	3 i.
	Glycerine.....	q. s. to dissolve.

M.

Dr. White then exhibited several instruments to be used in carrying out intra uterine medication.

INTRA-UTERINE MEDICATION BY IODIZED PHENOL.

DR. ROBERT BATTEY, of Rome, Ga., read a paper on the above subject, which consisted essentially in results obtained in a series of cases by the use of this agent, which he first brought to the notice of the profession in February, 1877. For ordinary purposes he recommended a solution of iodine in liquefied carbolic acid, in the proportion of 2 to 8. The energy of the solution was limited by the quantity used and the time it was allowed to remain in contact with the surface to which it was applied. It was rapidly absorbed and gave but little pain. The cervical glands were not destroyed by its use, and in no case within his knowledge had it produced stenosis.

The President called upon DR. J. MARION SIMS, of New York, to open the discussion on the papers by Drs. White and Battey.

Dr. Sims remarked, with reference to Dr. White's paper, that he was sorry the author had not mentioned the diseases in which he employed intra-uterine medication; and, with reference to Dr. Battey's paper, he was sorry the author did not continue to read the histories of the cases with which he illustrated his method of practice. The cases seemed to justify the means employed; yet, to him, it did not seem to be the best and quickest method of dealing with them. He thought, from his recollection of the histories as read, that in some of them the symptoms depended on the presence of fungoid granulations in the cavity of the uterus, and that any one of them might have been cured within four weeks simply by using the curette without intra-uterine medication. Certainly, with regard to time, treatment by the use of the curette would have been the most valuable, and, with regard to safety, he was not prepared to say that it was not quite as safe as intra-uterine medication by the use of

the remedy recommended. Carbolyzed preparations, in disagreeable odor, were second only to iodoform, which, on that account, he did not employ.

He had treated successfully several cases of uterine catarrh, in which there was present an albuminous secretion that persisted, despite ordinary treatment, by dilating the cervical canal, scraping the fungoid granulations completely away, and afterwards cauterizing the cervix up to the os internum by means of Paquelin's cautery.

DR. ISAAC E. TAYLOR, of New York, remarked that the course of treatment just mentioned by Dr. Sims was one which he had pursued for several years, and that he had given up all other methods. He used an iron heated a little above the dark color, and applied it rapidly to the part.

DR. WILLIAM T. HOWARD, of Baltimore, spoke of the importance of making a correct diagnosis, and the first thing he endeavored to do was to ascertain how far flexion, which was almost always present, extended. If it extended only to the os internum, the case was more easily controlled than when it extended beyond. He had not been able to effect a cure of the catarrh when there was present much flexion, especially of the body; but the first step in the treatment was to endeavor to correct the flexion, and then retain the uterus in position by means of a pessary. He had used Battey's preparation of iodized phenol, and in a large proportion of cases he had found it to be an efficient agent.

DR. FORDYCE BARKER, of New York, remarked, with regard to injecting the cavity of the uterus, that the use of the most bland fluid in that manner often produced the most intense pain in cases in which the size of the canal was normal, but not so in a uterus enlarged as in pregnancy. Therefore, in the treatment of hemorrhage after labor at full term or after abortion, there was perfect toleration of the injection into the uterine cavity; consequently in that class of cases intra-uterine injections were sometimes of great service. With reference to the value of the curette and intra-uterine medication, he thought they were not to be compared with each other as being applicable to the same class of cases. For example, metrorrhagia dependent on fungoid degeneration of the lining of the uterus, at the climacteric period as an illustration, could be best treated probably by the use of the curette; but metrorrhagia occurring at that period did not always depend upon that cause, and in that class the curette was of no service whatever, while intra-uterine medication might be employed with very great benefit.

Again there was a class of cases in which the uterus was flabby, as the result of impaired nutrition frequently associated with subinvolution, and in those cases he has been more successful in the use of intra-uterine medication than by the use of the curette.

He then related three cases of membranous dysmenorrhea which he had cured by means of intra-uterine applications of iodoform in the form of cones. First dilate the cervix, then introduce cones, one every other day. He showed a syringe to be used as an applicator.

DR. JOHN BYRNE, of Brooklyn, N. Y., remarked that success in intra-uterine medication depended entirely upon accuracy in diagnosis, not only with regard to the condition of the uterus, but more especially as to the question of etiology. The uterus in a normal or nearly approaching a normal condition would not tolerate with impunity any foreign substance in liquid form in its cavity, however bland it might be. The conclusion which he had reached was

that, if great accuracy in diagnosis was observed, intra-uterine medication, judiciously resorted to, was of immense value, and might be employed with perfect safety; that the farther the departure of the uterus from the normal to the pathological standard, the more tolerant it became of all medication and all interference; that liquid injections he had long since abandoned, with a single exception, namely, chloride of sodium water, after the use of the curette, securing a full, free return for the fluid.

The use of the curette was a successful method of treatment, but there were cases of uterine catarrh in which the cautery would succeed when the curette failed.

DR. PAUL F. MUNDÉ, of New York, remarked that, in the light of an experience in intra-uterine medication of various kinds in more than two thousand gynecological cases, he had long since discontinued the use of intra-uterine injections. He recommended Buttle's hard-rubber uterine syringe, which operated in precisely the same manner as the instrument described by Dr. Barker. Even from that, the most effectual, and also the most harmless manner of making intra-uterine applications through an undilated os, he had seen three cases of uterine colic with moderate shock, one (in which a solution of nitrate of silver $\frac{5}{i}$. to $\frac{3}{i}$. was used) so severe as to keep the patient in his office for several hours and necessitate a hypodermic injection of morphine.

DR. WM. GOODELL, of Philadelphia, objected to making incisions in the mucous membranes of the cervix before using the sponge-tent; the danger was from subsequent absorption of septic material.

With reference to intra-uterine medication, he had within the last three or four years been using it with a great deal more effect than formerly. He rarely uses the syringe by means of expression, but by injecting carefully and slowly the solution employed—four to eight drops of Calvert's No. 4 solution of carbolic acid, or Dr. Battey's solution with hydrate of chloral added. With reference to injections, if the womb was positively diseased, there was no harm from using fluid in its cavity, because the os was patulous; but if, as in a hysterical subject, it was difficult to determine whether or not the endometrium was diseased, they should be avoided. There was a class of cases in which he believed that the pain was due to fissure at the internal os, and such cases he had cured by forced dilatation of the cervical canal, and making a local application at that point.

DR. NATHAN BOZEMAN, of New York, thought sufficient estimate had not been placed upon displacements of the uterus as a factor in the etiology of uterine catarrh. His method of treatment was to first correct the displacement, and when that was done, although not entirely opposed to intra-uterine medication, he thought almost any kind of application might yield satisfactory results.

DR. H. P. C. WILSON, of Baltimore, believed that, when properly and gently administered, intra-uterine medication might be expected to yield good results, the same as were obtained by the local application of remedies to other mucous membranes, as to the throat, the urethra, etc. He thought one reason why we were not so successful as we might be in the use of intra-uterine medication was because of the imperfect manner in which the applications were made, improper manipulations, etc., and too much such medication was often a reason why we were not more successful. He had abandoned injections into the uterine cavity. He uniformly employed Sims's speculum and applicator.

DR. THADDEUS A. REAMY, of Cincinnati, remarked

that he had used Dr. Battey's preparation, but had abandoned it in consequence of its unpleasant odor. He thought that, in many cases of catarrh in which the uterus was enlarged and the disease had become chronic, great benefit was derived from dilating the cervix, independent of any consideration of being able to reach the cavity of the uterus, or of any consideration connected with medication of the cervical walls. In cases of what is commonly called incurable cervical catarrh, he had for many years dilated the cervix thoroughly with sea-tangle tents, and then applied Churchill's tincture of iodine, or some such preparation, and he had been pleased with the results obtained. The plan was, to dilate at different times, and make the local application. For villous degeneration, the use of the curette alone was not sufficient; the pressure from thorough dilatation should be added. He also disapproved of incising the mucous membrane of the cervix.

His treatment for membranous dysmenorrhœa was to use the wire curette only moderately sharp, when the first symptoms of menstruation manifest themselves, curetting the entire endometrium. He disapproved of injecting the cavity of the non-puerperal uterus.

THE PRESIDENT took the position that intra-uterine medication, carried above the os internum, should be given up as very hazardous, in many cases as very useless, and as a means of treatment which yielded disappointing results. He believed that, when uterine catarrh extended above the internal os, there was, as a rule, some special cause for it, such as flexure or version, and very commonly uterine congestion induced by only a slight degree of uterine descent. Treat the cause, and the secondary manifestation disappeared. In cases of fungoid degeneration following abortion or labor at full term, intra-uterine medication was so far inferior to the curette that it should not be adopted. The point of his argument was, that in all these cases there was generally something which gave rise to the symptoms, and when it was removed the symptoms would disappear.

The discussion was closed by Drs. White and Battey.

NOMINATING COMMITTEE.

The President appointed Drs. Fordyce Barker, Isaac E. Taylor, and W. L. Richardson as Committee on Nominations. He also appointed Drs. A. J. C. Skene and N. Bozeman as

AUDITING COMMITTEE.

The Society then adjourned to meet at 3 P.M.

FIRST DAY—AFTERNOON SESSION.

The Society was called to order by the President at 3 P.M.

The first paper was one on

THE TREATMENT OF PUERPERAL SEPTICÆMIA BY INTRA-UTERINE INJECTIONS,

presented by DR. E. W. JENKS, of Chicago, and read by the Secretary.

The paper contained an extended reference to the literature of the subject, the varying views which from time to time had been held, together with the author's conclusions.

DR. JAMES R. CHADWICK, of Boston, then read a paper entitled

IDIOPATHIC SEPTICÆMIA IN GYNECOLOGICAL PRACTICE.

In the term "gynecological practice" he included obstetrical, and defined septicæmia as a constitutional

disorder of limited duration, caused by the entrance into the circulation of a certain quantity of septic material [Burdon Sanderson]. As illustrating the character and symptoms of the disease, he gave the histories of five cases which had the following features in common: a denuded surface in the uterine cavity and chill; there was no pain, vomiting, or other sign of inflammation, but high fever, and the special symptom mentioned as belonging to most of that class of cases was an abnormal insensibility to pain, taken in conjunction with high fever.

He preferred to use permanganate of potash as a disinfectant, making a solution of a deep claret color. One special advantage of that agent was the change in color produced by the presence of putrid matter, the change being from deep claret color to deep yellow so long as putrid material was present. Injections into the uterus should be discontinued if chills followed. Danger from air entering into the sinuses was due to the amount entering, the entrance of a considerable quantity being required to do harm.

PUERPERAL SEPTICÆMIA.

DR. A. D. SINCLAIR, of Boston, then reported twenty-one consecutive cases of puerperal septicæmia which occurred in the Boston Lying-in Hospital. Of those nine died and twelve recovered. The cases illustrated direct contagion, and the *conditions favoring the invasion* were: prolonged and severe labors; 2, torn perineum or lacerated cervix; 3, retention of the foreign matter in the uterus; 4, nervous condition.

The treatment was: 1, quinine and cinchonism; 2, brandy to alcoholism; 3, nutriment, all that could be borne, in the shape of milk, beef-tea, egg-nog, etc.; 4, uterine douches of permanganate of potash and carbolic acid; 5, sponge-baths.

The douches were given every three hours. The brandy was given, in one case, $\frac{z}{ss}$, every half-hour without inebriation, and beef-juice and tea of six pounds of meat in one day.

The subject of puerperal septicæmia being before the Society, the President called upon

DR. GILMAN KIMBALL, of Lowell, Mass., to open the discussion. He remarked that, although he had seen a great deal of septicæmia following ovariectomy, he was yet ignorant of its nature, and of what to do for the patient when it occurred. One thing had struck him as remarkable, and that was, that some of the worst cases he had ever had—cases in which the discharges incident to ovariectomy had been of the worst character and most persistent, had really done the best; while in many other instances, in which there was no discharge at all, septicæmia or symptoms like those of septicæmia had developed, and fatal poisoning had gone on very rapidly. When it did occur, his chief reliance was on stimulants and nutriment.

DR. A. J. C. SKENE, of Brooklyn, believed that when we employed antiseptic management in puerperal cases, as was antiseptic surgery, we should improve in our results the same as had the general surgeons in theirs. He was inclined to think that the use of intra-uterine injections would become, if it had not already, very circumscribed indeed, and that in the future the authors of the papers would not use them so much as they had in the past. He also thought that intra-uterine injections were a means which could not be employed without danger; and, more than that, the use of the vaginal and uterine douche did not always guard against the occurrence of septicæmia after the uterus had been injured.

The discussion was continued by Drs. G. J. Engelmann, of St. Louis; Fordyce Barker, of New York; Paul F. Mundé, of New York; H. P. C. Wilson, of Baltimore; W. Goodell, of Philadelphia; W. T. Howard, of Baltimore; James D. Trask, of Astoria, N. Y.; A. T. Erich, of Baltimore, the President, and Dr. Chadwick.

The Society then adjourned to meet at 9.30 A.M. on Thursday.

THURSDAY, SEPTEMBER 18TH.—SECOND DAY—MORNING SESSION.

The Society was called to order by the President at 9.30 A.M.

INVITED GUESTS.

The following gentlemen were elected members by invitation: Dr. E. A. Atkinson, Dr. Thomas F. Murdoch, and Dr. John Dickson, of Baltimore; Dr. A. F. King, Dr. W. W. Johnson, and Dr. T. Hansmann, of Washington, D. C.; Dr. W. H. Geddings, of Aiken, S. C.; Dr. D. W. Lassiter, of Petersburg, Va.; Dr. F. Willhoft, of New Orleans, and Dr. W. W. Baird, of Washington, N. J.

The first paper was read by Dr. S. C. BUSEY, of Washington, D. C., and entitled

A CONTRIBUTION TO THE PATHOLOGY OF THE CICATRICES OF PREGNANCY.

The author of the paper began with a review of the literature of the subject, in which were presented the views of Credé, Schultze, and Hecker, which relate especially to the value of these scar-like streaks and spots, as a sign of existing or previous pregnancies. Then followed a discussion of the anatomy of the striae, and the nature of the lesion giving rise to those appearances. Dr. Busey reached the conclusion that the striae were not caused by rupture of the Malpighian layer, as generally believed, nor separation of the fibres of any of the layers of the skin. In conclusion, he maintained that the striae of pregnancy were localized atrophies of all the constituent layers of the integument, with compression and partial obliteration of the lymph-spaces.

On motion made by Dr. Barker, the discussion of the paper, which its high scientific character rendered impossible without special preparation, was omitted.

PROLAPSE OF THE OVARIES.

DR. PAUL F. MUNDÉ, of New York, read a valuable paper on the above subject, restricting his remarks to intrapelvic dislocation of the normal or but slightly enlarged ovaries. He reached the following conclusions, based upon observations made in 1,600 unselected gynecological cases:

1. The subject of prolapse of the ovaries had not received, in the text-books and periodicals, the attention which its importance as a separate affection demanded.

2. Ovarian prolapse, owing to the normal mobility of the organs, was a very common affection, frequently accompanying retro-displacement of the uterus, and in by far the greater number of cases the displacement was backwards into Douglas's pouch.

3. The normal, not markedly enlarged ovaries, frequently prolapsed, either in consequence of retro-displacement of the uterus, sudden jarring of the body, puerperal subinvolution, or menstrual congestion. More frequently still did prolapse occur in consequence of moderate enlargement of the ovaries through engorgement or inflammatory hyperplasia.

4. Their prolapsed conditions caused even normal ovaries, in time, to become hyperæmic, hyperplastic, and hyperæsthetic, partly through vascular obstruction and partly through the injuries to which they were subjected during defecation and coition. Already enlarged and degenerated ovaries, for similar reasons underwent a more rapid pathological change in consequence of their displacements.

5. In rare instances displaced ovaries had been found to become spontaneously replaced; thus, after the cessation of menstrual engorgement and through accidental favorable positions of the patient. As a rule, however, a displaced ovary required replacement by artificial means.

6. The symptoms caused by displacement of the normal ovaries, while more or less vague, were sufficiently severe to attract the attention both of the patient and the physician.

7. The diagnosis of ovarian prolapse was exceedingly easy to the practised touch *per vaginam*, rectum, or by conjoined manipulation.

8. The treatment consisted in replacing the organs manually, or by position, or by replacing the uterus, if displaced, which was readily possible if the ovaries were not adherent, and then retaining them in position by tampons or properly constructed pessaries adapted and moulded according to the needs of each individual case. If feasible, it was advisable in every case, to endeavor, first, to relieve the hyperæmia and hyperplasia so long as the organs were readily accessible.

9. Much ingenuity and patience might be required to devise proper means for supporting the inflamed and tender ovaries, which, once replaced, should be treated by the well-known remedies for chronic ovaritis.

10. If the ovaries were adherent the treatment resolved itself into antiphlogistic and narcotic measures. In cases of great local or constitutional disturbance, the last resort, their removal, might be suggested and adopted.

ANNUAL ADDRESS BY THE PRESIDENT.

The President, DR. T. GAILLARD THOMAS, of New York, then delivered the annual address on the subject—

THE GYNECOLOGY OF THE FUTURE AND ITS RELATION TO SURGERY.

The introductory portion of the address consisted of words of welcome on the pleasant reunion, reference to the influence of such societies, a tribute of respect to the late Miraduke B. Wright, M.D., of Cincinnati, Honorary Fellow, and a return of sincere thanks to the Society for the honor conferred upon him by electing him their presiding officer. He then passed to certain general considerations in reference to the department to which the members were especially devoting themselves, and followed with a notice of some of the chief influences which retarded gynecological and obstetric progress. Chief of the latter was the lack of facilities for demonstration of special views and operations. The result was, regarding clinical midwifery and gynecology, that a spirit of dogmatism had been creeping into our literature, that weakened them and gave strength to their opponents. It was the spirit of dogmatism that created so many diversities of opinion among pathologists with reference to points upon which all should agree, and gave to remedial measures such exaggerated prominence for short periods.

A few of the once popular remedial measures were mentioned, such as sponge-tents, cervical section, etc.,

but which to-day stood upon their proper basis as valuable diagnostic and surgical resources. No one familiar with Emmet's operation for trachelorrhaphy could doubt its beneficent results, and yet even that seemed destined to do a certain amount of evil before it stood upon reasonable middle ground. The proper use of such procedures as mentioned he did not criticize, but he censured all who adopted those, or any others, as cure-alls and overcame the doubts of the inexperienced by exaggerated and dogmatic assumptions.

Another great need, not only in the department of gynecology and obstetrics, but in general medical literature, was proper reviewing of books and pamphlets. The ringing tones of just and honest criticism, were rarely heard. He suggested that a standing committee on reviews be established, which should, as a body, pronounce judgment on current literature in their department. The opinion was still to a too considerable extent prevalent, that nearly all of the operations in obstetrics and gynecology could be as well performed by the general as by the special surgeon. Passing to the theme of his discourse, he remarked, that until 1850 gynecological surgery, justly speaking, had no existence; that all was uncertain as to principles. During the following decade it received a very great impulse. In 1846 amesthesia was given to man, and, Minerva-like, gynecological surgery sprang into renewed life at the hands of Simpson in Scotland, Baker Brown in England, Marion Sims in America, and Gustav Simon in Germany. It became subject to abuse, however, and to prevent the pendulum from swinging too far in an opposite direction, should it not be boldly asserted to the profession at large that gynecological and obstetric surgery stands to-day upon tenable, reasonable middle ground? He assumed that an enlightened conservative surgery was the pivot around which was to revolve the gynecology of the future. But he did not urge the claims of surgery at the expense of those of constitutional treatment in gynecology: the two should work together, if the greatest good was to be obtained; the one, however, never being substituted for the other. Medical and surgical gynecology were united by what the mechanic called dovetailing. The speaker then referred in severe terms to the body of men whose peculiar function was to decry every advance, to depreciate every effort at progress, and, under the fraudulent guise of conservatism, to smother every attempt at improvement by abuse and misrepresentation. A wise conservatism was like a compass to the mariner, but its "counterfeit presentment" was what he denounced. Recognizing and fully appreciating that the gynecological surgeons of our times were steadily advancing upon the road of progress, and assured that those procedures which had been most abused now stood upon the safest foundation, the Fellows were urged to strive without ceasing to bring more and more completely the pathology of their department under the domain of their senses and the control of their hands.

On motion made by DR. WHITE, of Buffalo, the thanks of the Society were extended to the President for his able address.

After the President's address, a paper presented by MR. T. SPENCER WELLS, of London, England, was read by the Secretary. It was entitled

A REPORT OF A SUCCESSFUL CASE OF BATTEY'S OPERATION.

The patient was aged 50 years, both ovaries were removed, and she recovered. The terrible pain from

which she suffered before the operation was not entirely removed, but sufficiently so to cause the woman to say that she had been paid for undergoing the operation.

Discussion upon Dr. Mundé's paper being next in order,

DR. ROBERT BATTEY, of Rome, Ga., remarked that he had not been able to connect prolapse of the ovary with disease of the organ in the relation of cause and effect. In by far the greater majority of cases, prolapsed ovaries were diseased, but on the other hand he called to mind numerous cases of diseased ovaries entirely unassociated with prolapse of the organ.

For the relief of ovarian and uterine pain he had employed "Mrs. Betts's utero-abdominal supporter" with great benefit.

The discussion was continued by Drs. Skene, Goodell, Bozeman, and Reamy; and on motion made by Dr. Albert H. Smith, of Philadelphia, was postponed until the afternoon session.

The Society then adjourned to meet at 2 o'clock P.M.

SECOND DAY.—AFTERNOON SESSION.

The Society was called to order at 2 P.M. by First Vice-President DR. H. P. C. WILSON, of Baltimore.

INVITED GUESTS.

The following gentlemen were elected members by invitation: Drs. James E. Morgan, F. Howard, S. O. Ritchie, of Washington, D. C.; and Dr. Hunter, of Martinsburg, Va.

The next business in order being the discussion of Dr. Mundé's paper.

DR. FORDYCE BARKER, of New York, remarked that in treatment the thing to be accomplished was to restore the organ, as far as possible, to its normal position, to keep it there, and to obviate or remove all the causes which developed or perpetuated that pathological condition.

Attempts at replacing the prolapsed organ were not always successful, yet it is always worth while to make the attempt; and for overcoming plastic exudation, he suggested hot-water injections and the use of mercury in the form of minute doses of the protoxide continued for some time.

To retain the organ in position he recommended the cotton tampon, aided by a solution of tannic acid, equal parts with water.

To correct the habit of constipation, he was accustomed to give a laxative composed of equal parts of sulphate of magnesia, carbonate of magnesia, tartrate of potassa, and sulphur.

DR. S. C. BRISSEY, of Washington, D. C., remarked that his experience corroborated almost entirely that expressed by the author of the paper. From his experience he would say, however, that structural changes in the ovaries were secondary, and usually secondary to displacement of the uterus. He thought that external abdominal support acted by restoring the equilibrium of pressure which the superincumbent viscera exerted on the pelvic organs.

DR. ALBERT H. SMITH, of Philadelphia, thought that if the subject of prolapse of the ovaries received more fully recognized, and more careful examination made with regard to that condition, there would be a lesser number of cases in which the patient went about from one physician to another, and submitted to one and another form of treatment. He thought that, in most cases of prolonged pelvic trouble, painful in character, and in which various methods of treatment had been adopted without benefit, prolapse of the ovaries

was the pathological condition present. He had not seen good results from the treatment of prolapsed ovaries by means of pessaries. He had obtained the best results from the use of a simple bag of tarlatan stuffed with tannic acid. There were many cases, doubtless, which could not be relieved unless it was by means of Dr. Battey's operation.

The discussion was continued by Drs. Chadwick and Battey, and was closed by Dr. Mundé.

DR. JOHN BYRNE, of Brooklyn, read the next paper, which had for its title

KOLPO-CYSTOTOMY BY GALVANO-CAUTERY.

Kolpo-cystotomy as a means of restoring continuous artificial drainage of the bladder was an American operation. The author then gave a history of the operation, and exhibited his instrument by means of which it could be performed without the destruction of tissue beyond the outline of its blades. He had not used the thermo-cautery, believing it to be dangerous and unsuitable for operations in cavities among delicate structures, even when guarded by Wilson's jacket.

The paper being before the Society for discussion,

DR. HENRY J. GARRIGUES, of New York, remarked that he could not entirely endorse the criticism offered by Dr. Byrne regarding the thermo-cautery. From personal experience he was not aware that the radiating heat was less from the galvano cautery than from the thermo-cautery. That, however, could be determined by physical experimentation.

The paper was also discussed by Dr. White, and the discussion was closed by Dr. Byrne.

The next paper was one presented by DR. ISAAC E. TAYLOR, of New York, but, on account of lack of time, was not read. Its title was

COMPLETE CONGENITAL AND ACCIDENTAL ABSENCE, OR ATRESIA OF THE VAGINA IN THE PREGNANT AND NON-PREGNANT FEMALE; TREATED BY THE TEARING OR LACERATING PROCESS,

and the following is a brief abstract.

The treatment of this class of cases had always been regarded by surgeons as difficult, and as liable to give rise to serious, if not fatal results. Whatever the exact nature of the defect might be, it was conceded that the accidents which caused death when the operation was performed were nearly identical.

The vagina might be totally or only partially absent. In some instances the vagina had an opening into the rectum, the anus, or the urethra, and pregnancy occurred.

Dr. Taylor then related a case of complete congenital atresia of the vagina, with pregnancy and safe delivery of a living child. It was treated by the tearing process with the finger-nail. The mother made a good recovery. In that connection he presented the case reported by Dr. R. P. Simmons in the *St. Louis Medical Examiner*, in February, 1847. In that instance the knife was used, and the child was safely delivered. Dr. Simmons asked the question, and Dr. Taylor joined in the query. How did the menstrual fluid find its exit in either case from the uterus, and by what law of the animal economy did conception take place? Was there a vicarious secretion from the inner surfaces of the labia pudenda or contiguous parts, or did the menstrual fluid permeate the fibrous structure blocking up the whole of the vagina? These were cases of atresia not traceable to either disease or accident, in which the vagina was almost closed, the most careful examination, however, failing to detect the minutest opening.

Dr. Taylor did not adopt the opinion that a vicarious discharge or transudation of menstrual fluid occurred through the dense fibrous structure, or through the anus, or through the bladder. The opening was sometimes so small that it was recognized, if recognized at all, only with the greatest difficulty.

For this class of cases, Dr. Taylor recommended operative procedure, which consisted in tearing the tissues. His first operation was in 1866, in the pregnant, and in 1867 in the non-pregnant. Dr. Emmet had published, in 1866, three cases in which the opening was made by the tearing process, but of these cases Dr. Taylor did not know when he operated. Amussat's case was published in 1835, and the operation was made by the tearing process in 1832. M. Debrou treated a case in the same manner in February, 1847, and published it in March, 1851, but he was anticipated by Simmons in this country, who operated in November, 1846.

He disapproved entirely of operating through the rectum in either class of cases. If the obstruction was epithelial or connective tissue, the tearing or lacerating process by the finger-nail, or a convenient instrument, would succeed. If the structure was dense, recourse must be had to the knife, trocar, or scissors. Dr. Taylor preferred to operate when the uterus was quiescent, and pressure on the uterus for evacuating accumulated menstrual fluid should be avoided. Forceful injection of the uterus with warm water should be avoided. He believed that in such cases, after an operation, marriage was permissible. In cases in which the atresia existed in the pregnant, he believed it would be safer to defer the operation until the labor began, than to operate earlier.

MEASUREMENTS OF THE UTERINE CAVITY IN CHILD-BED

was the name of a paper then read by Dr. A. D. Sinclair, of Boston. It contained an analysis of 108 cases, and was mostly statistical. The average length of the uterine cavity in the 108 cases was 3.02 inches. The average length of the uterine cavity in 75 primiparæ was 2.94 inches. The average length of the uterine cavity in the 33 multiparæ was 3.21 inches.

The Society then adjourned to meet on Friday, at 11.30 A.M.

FRIDAY, SEPTEMBER 19TH.—THIRD DAY—MORNING SESSION.

The Society was called to order at 10.30 A.M., by the President.

THE EARLY APPLICATION OF THE FORCEPS IN THE FIRST STAGE OF NATURAL LABOR.

DR. ISAAC E. TAYLOR, of New York, read a suggestive paper on the above subject, which embraced the following views: He distinguished natural from lingering or protracted labor. In natural labor the soft structures yielded kindly and without injury, while in tedious and prolonged labor they became irritable, congested, and œdematous, and there was imminent danger of injury being produced. Interference in the process of labor, when it was going on well, was unjust and reprehensible. The views entertained by Nægele, Ramsbotham, Collins, and Schroeder, regarding interference in the *second* stage of labor, Dr. Taylor regarded as extravagant fears of mischief, and he thought no intelligent practitioner of the present day would yield to such doctrines. Those writers, however, had ignored the *first* stage of labor, and believed that no harm followed its continuance for from 60 to 160 hours, so long as the membranes were entire

and the liquor amnii not escaped. From that view Dr. Taylor dissented, and asked, "Are the structures of the powerful and hard-taxed uterus, body, and cervix of no value? Is the pressure of the child's head on the lower part of the body of the uterus or the superior part of the cervix, when the head is capped by the cervix itself, the pains active and steady, and no advance made for some hours, of no moment? When is nature to cease pegging away?"

The practice in such cases, which he had followed for nearly eighteen years, if the uterus did not relax, and the head of the child did not adapt itself properly to the os, membranes ruptured or unruptured, even though the os was not open more than one or one and a half inches, and no unfavorable symptoms, except the fact that the labor did not progress, was not to place his patient under "the ban of time," but proceed to abbreviate the *first* stage the same as he would a prolonged *second* stage of labor, and he did it in the following manner: he introduced his thin, narrow-bladed forceps (the ordinary forceps being too wide), and brought the head of the child properly in contact with the undilated cervix and lower part of the body of the uterus without using any forcible traction whatever. The obstruction was at the upper part of the cervix. The os might be dilatable or not, but unaided nature could not overcome the difficulty in the cervix, and sometimes sought relief by rupture of the uterus at that point. To deliver such cases safely sometimes required one or two hours, or even more, but yet the whole length of the labor was very much shortened. The object of the forceps was simply to retain the head of the child in contact with the os uteri during and after a pain, and in some cases to aid in flexing the head so that the occiput might become the natural dilator of the cervix. After fifteen or twenty minutes, if the os uteri was found to be more dilated, the forceps were removed at the beginning of a pain, and the head sometimes effected the dilatation sufficiently to escape through the os, and then the labor progressed, and was completed, naturally or otherwise, according to circumstances. The forceps might be reapplied a few minutes after their removal, and so the relay treatment might go on, and the forceps be applied and reapplied three or four times. The inexperienced in the management of these cases should not resort to the forceps unless they had had some practical experience in their use in the *second* stage of labor. It was equally important to know when to cease traction.

The "novelty" of the propositions had passed away, the "revolutionary" change had taken place, and the "innovation" had existed since 1863, although Dr. Johnston, without giving due credit to its originator, had adopted the method in 1871, and had been convinced of its great value in saving the life of both mother and child in 113 such cases. In experienced hands, the operation, if carefully and skilfully performed, was a safe procedure, and illustrated the "scientific frontice." Every obstetrician should know *why, when, and how* to interfere in the parturient process.

The paper was discussed by Drs. White of Buffalo, Howard of Baltimore, Reamy of Cincinnati, and Dr. Taylor.

DR. WILLIAM GOODELL, of Philadelphia, then read a paper entitled

CLINICAL NOTES ON THE ELONGATIONS OF THE CERVIX UTERI.

In this paper, the author gave his views with regard to the etiology and pathology of the two forms of

prolapsed of the womb, viz., the elongation of the supravaginal portion of the cervix, and that of its intravaginal portion. The former he regarded as due to the traction of a prolapsing bladder and vagina upon a womb made ductile either by subinvolution or by chronic congestion. He believed that that form of elongation was not congenital, but acquired. The author had, however, seen it once in a sterile married woman, and twice in virgins who had passed the climacteric.

In view of the very unsatisfactory results from the usual operative treatment of that very frequent form of prolapse, the author gave the history of twelve of his cases, these being the only ones of which he could keep track for any length of time. Each one had the vaginal portion of the cervix cut off, either by the cold wire or by the hot wire, and in each one the utero-vaginal outlet was narrowed by the operation of colpo perineorrhaphy. The wire was used because, in the author's opinion, some suppurative action was needed to bring on retrogressive metamorphosis in the redundant portion of the cervix. The results were as follows:

Three women, since the operation, had been under observation for from five to six years, and had remained cured. Four women had thus far kept well for from two and a half to four years. Three women had not, up to the present time, exhibited the slightest symptoms of relapse, for six months, for one year, and for one year and a half respectively.

One woman, after staying well for four years following the operation, became pregnant and gave birth to a living child. Her perineum was again torn, and the bladder and vagina were beginning again to prolapse. One woman was cured of the cervical prolapse, but not of her cystocele or of her rectocele.

In the amputation of the cervix, the author preferred the cold wire to the hot one, because the danger from secondary hemorrhage was much less, and because the surrounding mucosa could be slid over and stitched to the stump, to which it would unite by granulations, and thus lessen the area of cicatricial contraction.

Elongation of the intravaginal portion of the cervix the author deemed either a congenital affection or an exaggeration of a congenital affection. True longitudinal hypertrophy he considered as essentially an affection of virgins or of sterile women. Of this variety he has seen seven cases in which the cervix either appeared at the vulva or protruded from it. Under the form of conical cervix, it was, however, very frequently met with, but the elongation was then limited.

With regard to the indications for the treatment of this elongation there could be no question. Since suppurative action was not needed, the redundant portion ought to be cut off by a sharp instrument, and not by the cold or the hot wire. The surrounding mucosa was then sewed to the mucosa of the os uteri by radiating stitches, which will prevent cicatricial contraction.

DR. J. C. REEVE, of Dayton, Ohio, opened the discussion by remarking that there were two points to which he wished to call attention:

1. The paper presented cases from actual practice upon a subject concerning which there was a great diversity of opinion.

2. If he correctly understood the subject, it was the prevailing doctrine that all the evil effects which followed laceration of the cervix were mechanical. To that doctrine, however, he did not subscribe, but believed that the evil results were due to such conditions as subinvolution, and others produced by the

injury to the cervix. To the preparatory treatment required he was inclined to give the credit of cure fully as much as to the surgical operation.

DR. ALEXANDER DUNLAP, of Springfield, O., remarked that he had never met with a case of supravaginal elongation of the cervix. He had met with cases in which there was intravaginal elongation of the cervix, and in one the projection was nearly two and a half inches, produced sterility, and had very much the feel and appearance of the male organ. In that case he gave directions regarding sexual congress, so that the semen might be brought in direct contact with the mouth of the elongated cervix. Pregnancy occurred, and the woman subsequently bore children without hindrance. He would not, therefore, recommend amputation in all cases, certainly in married women.

DR. A. J. C. SKENE, of Brooklyn, remarked with regard to treatment, that he had followed that recommended by Dr. J. Marion Sims, and that he was fully satisfied with the results obtained. He was confident, so far as his own experience went, that Dr. Reeve was perfectly right regarding mechanical irritation. He did not believe that the good result depended entirely upon the suppurative that followed the operation, for oftentimes the hypertrophy rapidly disappeared when only a very small portion had been removed and there was only a trifling amount of suppuration.

The discussion was continued by Dr. Isaac E. Taylor, of New York, and closed by Dr. Goodell.

THE PRINCIPLES AND PRACTICE OF GYNECOLOGY AS RELATED TO INSANITY IN WOMEN.

DR. A. J. C. SKENE, of Brooklyn, presented a valuable paper on the above subject, which would have been read had time permitted. The following is an abstract.

In making observations in gynecological practice in the Brooklyn Insane Asylum he had met with an entirely new phase of practice, in which the ordinary methods of investigation were of little value. He was obliged to devise a new method of examining patients, and the system of investigation adopted and the phenomena observed, together with the deductions drawn from them, formed the subject-matter of his paper. He restricted his discussion to the relations which gynecology bore to insanity.

With reference to the way in which diseases of the sexual organs caused insanity, the rule has been to attribute insanity, when developed during the existence of uterine or ovarian disease, to reflex action. No doubt that was an important factor in the cause of mental derangement, but it was far from covering the whole ground. There were many cases of insanity that could be traced to the sexual organs, but in which reflex action took no part.

One of the most marked and important causes of insanity in women was clearly traceable to frequent child-bearing and lactation among the poorer classes. That he had proved by clinical observations. There was too little in our literature on the subject of mania caused by the exhaustion of the nervous system from child-bearing and nursing. Our books told us of anemia from prolonged lactation, but said little of the nervous exhaustion which might or might not accompany the anemia.

From cases in his own practice he was satisfied that occasionally the normal functional activity of the reproductive organs tended to undermine the brain and nervous system to an extent sufficient to lead to insanity.

He was also satisfied that the prevailing opinion

that insanity, as the result of reflex action, occurred very frequently at puberty and the menopause, was not always true. The point which the author of the paper made was that a clear distinction should be drawn etiologically between insanity caused by existing active disease of the sexual organs and insanity arising from brain-exhaustion produced by prolonged or excessive functional activity of those organs while free from disease, and he inclined to the opinion that as many or even more cases could be traced to the latter as to the former.

To the question, "What is the effect of insanity upon the function of the reproductive system?" Dr. Skene gave the formulated answer, that well-developed insanity with impaired general nutrition caused suppression of the functions of the sexual organs; that deranged innervation tended to produce the same result; that, in mild forms of insanity, menstruation might continue normal; that excessive menstruation among the insane was usually caused by uterine disease, and should be accepted as evidence of such.

To the question, "What effect did insanity exert upon diseases of the sexual organs?" he gave the answer that insanity tended to cure *functional* diseases of the uterus, but that such a conclusion could not be applied to other forms of local disease of an *organic* character. Organic diseases of the sexual organs tended to retard the recovery, but very much relief could be afforded in such cases by the art of gynecology.

To the question, "What are the ascertained effects upon the insane, of curative treatment regarding co-existing diseases of the sexual organs?" the doctor gave the following answer: that the acute affections of the brain and nervous system, wholly due originally to disease of the sexual organs, would be relieved in a large majority of cases by curing the primary affection, and the general condition of insane women would be improved by restoring the sexual organs to health.

Dr. Skene then directed attention to the question of *diagnosis* among the insane, and spoke of the difficulties of obtaining requisite clinical information. Physical examination had been beset with difficulties. Ether as an anæsthetic had been practically unsatisfactory. He used nitrous oxide gas, and had found that it answered the purpose admirably. The physical signs of disease varied but little from those found in ordinary cases. There was marked absence of tenderness, the vagina and cervix in cases of some standing were found to present the appearance seen after the menopause, and the rectum was, as a rule, impacted.

The diseases which occurred were not peculiar or worthy of special notice, and the treatment of diseases of the reproductive organs among insane women was based upon the general principles which guided us in ordinary practice, with such modifications as the peculiarities of this class of cases might demand.

DR. J. TABER JOHNSON, of Washington, D. C., then read a paper on

MISMANAGED LABOR THE SOURCE OF MUCH GYNECOLOGICAL PRACTICE.

He referred to the wonderful achievements and rapid growth of gynecology. Diseases were now completely relieved which a generation ago were considered incurable. The diseases of women have greatly multiplied, until it was nearly as difficult in this day to find a perfectly healthy woman as it was for Diogenes, in his age, aided by his lantern, to find a perfectly honest man. The doctor thought that there was a tendency

in the minds of the profession to the study of gynecology, to the neglect of the more important department of obstetrics, and illustrated his statement by referring to the fact that, of the seventy-one papers in the three volumes of the Society's transactions, only sixteen of them related to obstetrics, and that of the sixty-one articles and discussions in the July numbers of the American and British obstetrical journals only twenty of those were devoted to obstetrical subjects. He referred to midwifery as the more important branch, "because, while in the former (gynecology) we render our patients much more comfortable, and at times prolong life; in the latter (midwifery), by our operations and skill we not only save maternal and fetal life at the same time, but prevent the necessity of our patients calling upon the gynecologist in the future at all, by preventing the occurrence of those conditions requiring their aid."

The object of the paper was stated to be to draw attention to the fact that gynecology derived much of its prominence and importance from the mismanagement of obstetrical cases and faulty treatment during the puerperal month. There was a growing tendency among general practitioners in the direction of assuming the responsibility of severe obstetrical operations and treatment without skilled counsel, which was not apparent in the field of gynecology. If the experienced accoucheur is not always able to avert danger, damage, or death, how much less could those who only occasionally attend cases of confinement, and are not acquainted with recent obstetrical text-books and literature.

A lengthy reference was made to the faulty management of abortion and its subsequent treatment, in allowing the placenta and secundines to remain undelivered in cases requiring manipulation for their removal.

The doctor declared that a patient was entitled, while undergoing the agony and enduring the exhaustion of lingering or difficult labor, to the best of skill and the most improved instruments, and that the physician who attempted the performance of the capital operations in obstetrics without those necessary factors of success, when they were within his reach, assumed a very grave responsibility.

The paper closed with an appeal for a greater study of obstetrics and its clinical teaching in our colleges in the future, as the best means of preventing many of the conditions which we have to treat in gynecology.

The Society then adjourned to meet at 3 P.M.

THIRD DAY—AFTERNOON SESSION.

The Society was called to order at 3 P.M. by the President.

The first paper was read by DR. J. C. REEVE, of Dayton, Ohio, and consisted of a

REPORT OF A CASE OF EXTRA-UTERINE PREGNANCY—TREATMENT BY THE USE OF ELECTRICITY.

The case was treated successfully by the use of electricity, beginning at what was presumably the end of the third month of pregnancy. It was applied daily, from the 28th of March until the 5th of April. On the 15th of April the patient was decidedly better. On the 11th of May there was a marked change in the condition and appearance of the breasts—more flaccid. June 4th, the tumor was much higher than formerly; oblique diameter decreased two-thirds; menstruation repeated. August 1st, sound introduced, and uterus found to be of normal depth.

The subject of extra-uterine pregnancy was then

discussed by Drs. Wilson, Howard, Reamy, White, Mundé, Battey, and the President.

A NEW METHOD OF PERFORMING DECAPITATION

was the title of a paper presented by Dr. W. L. RICHARDSON, of Boston.

The object of the paper was to show: *first*, that in all cases in which there is no hope of saving the life of the child, the condition of the mother is such as to necessitate operative interference; the child cannot be delivered easily, either by the forceps or version, and if the neck of the child can be reached, the operation of decapitation is indicated. *Second*, this operation is then best performed by means of the decollator of Carl Braun and the decapitating knife of Rumsbotham—the former being used to break the vertebral column, and the latter to divide the soft cervical tissues.

KOLPOCEPETASIS VERSUS KOLPOKLEISIS, AS ILLUSTRATED IN A CASE OF ATRESIA OF THE VAGINA WITH RECTO-UTERO-VAGINAL FISTULE,

was the title of a paper presented by Dr. NATHAN BOZEMAN, of New York, which would have been read had the time permitted. He used the word kolpocepetasis (to stretch the vagina) in contradistinction to the word kolpokleisis (to close the vagina). The case reported illustrated the meaning of both terms.

The following papers were read by title:

"The Relations of Symptoms to Versions and Flexions of the Uterus." By Dr. E. Van de Walker, of Syracuse, N. Y.

"The Justo-Minor Pelvis, with the Report of a Case." By Dr. W. T. Lusk, of New York.

"Chronic Inversion of the Uterus." By Dr. W. H. Byford, of Chicago.

"The Analysis of Five Hundred Gynecological Cases." By Dr. G. H. Bixby, of Boston.

"In Memoriam—Marmaduke B. Wright, M.D." By Dr. T. Parvin, of Indianapolis.

The hour for adjournment having arrived, the President, Dr. T. G. THOMAS, expressed his gratification over the success of the meeting, and, thanking the Fellows for the uniform courtesy extended to him, resigned the chair in favor of his successor, Dr. J. Marion Sims, of New York.

Dr. Sims took the chair, and, with a few appropriate words, accepted the presidency of the Society.

On motion, made by Dr. H. P. C. WILSON, of Baltimore, the Society tendered to Dr. Thomas its thanks for the impartial manner with which he had presided over its deliberations.

Dr. Thomas made an appropriate response.

Dr. Wilson gave notice of a proposed amendment to the constitution and by-laws, to the effect that, hereafter, the officers shall be nominated in open Society, and not by a committee on nominations.

The President then declared the Society adjourned to meet on the *first* Wednesday in September, 1880, in the city of Cincinnati.

The following are the officers elected for the ensuing year:

President: Dr. J. MARION SIMS, of New York.

Vice-Presidents: Dr. ROBERT BATTEY, of Rome, Ga., and Dr. W. T. HOWARD, of Baltimore, Md.

Council: Drs. W. GOODELL, of Philadelphia; E. W. JENKS, of Chicago; A. D. SINCLAIR, of Boston, and A. J. C. SKENE, of Brooklyn.

Secretary: Dr. JAMES R. CHADWICK, of Boston.

Treasurer: Dr. PAUL F. MUNDÉ, of New York.

The following gentlemen were elected Fellows: Dr. John Scott, of San Francisco; Dr. Edward L.

Duer, of Philadelphia; Dr. R. Stansbury Sutton, of Pittsburg, Pa., and Dr. J. W. Underhill, of Cincinnati, O.

The time for holding the annual meeting was changed from the third to the *first* Wednesday in September.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 5 to October 11, 1879.

SUTHERLAND, CHARLES, Colonel and Surgeon. To report in person to the Comd'g General Mil'y Division of the Pacific, for duty as Medical Director of that Division. S. O. 229, A. G. O., Oct. 4, 1879.

IRWIN, B. J. D., Major and Surgeon. To report in person to the Comd'g General, Dep't. of Dakota, for assignment to duty. S. O. 229, C. S., A. G. O.

WOLVERTON, W. D., Major and Surgeon. To report in person to Comd'g General Dept. of Dakota, for assignment to duty. S. O. 229, C. S., A. G. O.

MUNN, C. E., Capt. and Asst. Surgeon. To report in person to the Comd'g General Dept. of the Missouri, for assignment to duty. S. O. 232, A. G. O., Oct. 9, 1879.

FINLEY, J. A., 1st Lieut. and Asst. Surgeon. Granted leave of absence for four months. S. O. 230, A. G. O., Oct. 6, 1879.

MOSELEY, E. B., 1st Lieut. and Asst. Surgeon. Having reported in person, relieved from duty at Fort Robinson, Nebr., and to report in person to the Dept. Comd'r at Rawlins, Wy. T. S. O. 89, Dept. of the Platte, October 6, 1879.

BIART, V., 1st Lieut. and Asst. Surgeon. Granted leave of absence for one year on surgeon's certificate of disability, to take effect Oct. 1, 1879, with permission to go beyond sea. S. O. 232, C. S., A. G. O.

APPEL, A. H., 1st Lieut. and Asst. Surgeon. To report to Fort Benton, M. T., and to report to the Post Commander for duty as Post Surgeon. S. O. 106, Dept. of Dakota, Sept. 30, 1879.

PHILLIPS, H. J., Capt. and Asst. Surgeon. Died at New York City on October 10, 1879.

Obituary.

EUGENE PEUGNET, M.D.,

FORDHAM, NEW YORK.

DR. EUGENE PEUGNET, of Fordham, N. Y., died in his forty-third year, Friday, October 10, 1879. The day previous, while walking on the railroad track, near Mt. Vernon, N. Y., he was run over by the locomotive of an express train, which crushed and partially severed both lower extremities. When picked up he was perfectly conscious, and, with a full appreciation of his desperate condition, gave directions for the treatment of his case, and even discussed with his friends the character of amputations necessary. At his request, the amputations were performed, but he sank and died a few hours afterward. Dr. Peugnet received his preliminary education in New York, and at an early age attended lectures at the College of Physicians and Surgeons, graduating from that institution in March, 1858. After serving a term of internship in Bellevue Hospital, he commenced practice in this city. At the breaking out of

the war he went to the field as Surgeon of the 71st Regiment, was captured at Bull Run while heroically attending the wounded, and was imprisoned for a considerable time in Richmond, Va. After the war he removed to Fordham, where he continued actively working in his profession until his death. His contributions to science were in the shape of many well-written papers, which were published in *THE MEDICAL RECORD*, *N. Y. Medical Journal*, and *American Journal of Medical Sciences*. He was a careful student, a terse writer, and possessed an eminently logical mind. He was a member of the different medical societies of this city, and was an active worker in them. As a practitioner he enjoyed a large patronage, and was alike kind to his patients and scrupulously honorable to his professional brethren. His funeral services were held at the Church of St. Vincent de Paul on Monday, October 13th.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 11, 1879.

Week Ending	Typhus Fever.	Typhoid Fe- ver.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Oct. 4, 1879. . . .	0	11	34	1	14	20	0	0
Oct. 11, 1879. . .	0	14	36	3	21	33	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from October 8th to October 14th, inclusive, was 76, and the number of deaths that occurred was 37. The total number of new cases for this year to October 15th is 1,479, and the total number of deaths, 517.

OUT-DOOR POOR RELIEF.—For the purpose of affording medical relief to the out-door poor, Cincinnati is divided into twenty-five districts, with a physician attached to each district. These physicians make annually between two and three thousand professional visits. Most of the visits are to persons who would, without them, be obliged to go to a city hospital. Thus, much money is saved to the city and greater satisfaction afforded, in most cases, to the patients. Such systems, more or less modified, exist in many other cities, and they might be still further extended with great saving to the city purse.

THE AUDIPHONE.—This is a new instrument for assisting the hearing of the moderately deaf. It consists of a flexible sheet of hard rubber with a handle attached, the whole resembling very much an ordinary fan. A string is attached in such a way that the rubber plate can be bent over towards the handle to a greater or less curve. The instrument is held in the hand and the top edge laid against the teeth, the convexity of the curved plate being out. The apparatus is quite ornamental, and is probably of assistance in some forms of deafness.

MEDICAL COLLEGE OF THE UNIVERSITY OF VERMONT.—This college graduated a class of forty-nine at its last commencement, having rejected fifteen per cent. The total number of students in attendance was 151.

SEA-SIDE SANITARIUM.—This institution has done a larger work this summer than ever before. Nine thousand five hundred sick children have been taken out on excursions. Sixteen hundred and twenty-five children have spent a week at the Sanitarium; the total cost has been only \$6,425.

THE LEPER IN THE MIDDLE AGES.—Among the Christians in the Middle Ages a leper died in the eyes of the law as soon as he became a leper, and the church had a burial service read over him. After this he was separated from men and was virtually dead to this world.

HARVEY'S REMAINS.—It was proposed a year ago to have Harvey's remains removed to Westminster Abbey. Nothing has yet been done towards this, however. The church where they now lie is not in good condition, the vault is wet, and coffin covered with stones.

CHOLERA IN INDIA.—Cholera has broken out among the British troops advancing into Afghanistan.

VERMONT PHARMACEUTICAL ASSOCIATION.—The tenth annual meeting of the Vermont Pharmaceutical Association was held at Burlington, October 7th and 8th.

ALEXIS ST. MARTIN.—It is comforting to learn that this much-talked-of individual is still alive and hearty. He is living at St. Thomas, Province of Quebec, Canada.

NATIONAL BOARD OF HEALTH.—Dr. H. I. Bowditch has written a letter to the *Boston Medical and Surgical Journal* defending the National Board of Health from the many attacks it is now receiving. Dr. Bowditch is convinced that the board has worked hard and economically during the past summer. He is also much impressed with the care that is taken in expending the money at its disposal. As an example, he states that in a bill for personal expenses, the item "for washing" was struck out and disallowed. He credits the board also with having, to a very large extent, prevented the spread of the fever beyond Memphis.

INSANE ASYLUM CONSULTING BOARD.—Board of Consulting Physicians and Surgeons appointed for the Insane Asylums of the Department of Public Charities and Correction: Drs. James R. Wood, Austin Flint, Jr., E. G. Janeway, M. A. Pallen, A. McL. Hamilton, C. I. Pardee, J. P. P. White, A. L. Loomis, Whitman V. White.

A NEW MEDICAL SCHOOL.—The College of Physicians and Surgeons—has recently been organized in St. Louis. It opens with a preliminary examination, and promises to demand a high grade of scholarship.

DR. L. P. YANDELL, who has been travelling in Europe and writing home very interesting letters to the *Medical News*, has just returned to his home in Louisville.

THE NEW HAMPSHIRE MEDICAL SOCIETY held its semi-annual meeting on Sept. 17th and 18th. Prof. Hubbard read a paper on the "Life and Character of Nathan Smith." Prof. Dunster gave a lecture upon the "Discovery of Anæsthesia." Other interesting papers were presented.

LIBRARY OF THE FACULTY OF MEDICINE IN PARIS.—This library contains nearly 60,000 volumes, many of them being very ancient works. A new catalogue has recently been completed.—*East. Med. and Surg. Jour.*

Original Lectures.

TYPHOID FEVER IN INFANCY AND CHILDHOOD.

A CLINICAL LECTURE DELIVERED IN BELLEVUE HOSPITAL,

By A. JACOBI, M.D.,

PROFESSOR OF DISEASES OF CHILDREN IN THE COLLEGE OF PHYSICIANS AND SURGEONS IN NEW YORK CITY.

(Reported for THE MEDICAL RECORD.)

PART I.

GENTLEMEN:—Some of you, it may be, saw this boy last Wednesday. He then presented himself at my clinic at the College of Physicians and Surgeons, and at that time we made the diagnosis of a complication of broncho-pneumonia with typhoid fever. To-day we shall see whether that diagnosis was correct, and for the purpose of determining that question, let me state what his symptoms then were. As he told his story, he remembered that for a number of days he had a sense of chilliness and cold along the back and extending over the whole body. He complained that he was easily fatigued, that he was tired all the time, and that he had a cough at a very early period of his sickness. He had on Wednesday last all the symptoms of pneumonia, partly bronchial and partly interstitial. I found upon one side of the chest somewhat diminished respiration, a few râles, and a very slight amount of dulness upon percussion; no pleural friction-sound. The dulness extended as far as diminution of the respiratory murmur was rather marked. We reached the diagnosis of pneumonia, chiefly bronchial in character. A few minutes later he was again examined, when it struck me that he had symptoms which, to a certain extent, complicated the diagnosis made. I found, when he was laid upon his back, that he complained of slight pain in his right hypogastric region, over the ileo-caecal valve, and there was also some gurgling present. I also found a few rose-colored spots in the same region, and now at various points over the chest and abdomen a few spots of the same character can still be seen. At that time it was found that the spleen extended longitudinally more than three and a half inches. It now measures, in the same direction, eight centimetres. I remember also that his temperature was 103° F. (39.5° C.). It was taken at about this hour in the afternoon, and we will now compare it with the record which the thermometer gives to-day. The rectal temperature is now 102½° F.

Let us compare the other symptoms found five days ago with those of to-day.

The temperature is less; there is less dulness all over the left lung; the respiratory murmur is less diminished; and there are less râles than existed last week. Evidently his pneumonia is improving. Furthermore, the spleen is a trifle smaller than it was. The roseola is not so well developed, only a few spots being visible. The pain and gurgling in the right iliac fossa have disappeared. He says that his cough is better, and that he feels better.

I have selected this case for the purpose of directing your attention to a number of cases seen in infancy and childhood, and in which it is not always easy to arrive at a correct diagnosis.

Not infrequently will you see such cases when they are of two or three weeks' standing, and it will be found

that the child has been a little languid, has had slight fever, and been a little morose and peevish in the afternoon and evening. In the morning it has probably seemed quite well, but the same symptoms have returned in the after part of the day, and finally, at the end of a week or two, the child in the meantime getting no better, the parents become anxious and send for a doctor, who is expected to make a diagnosis without delay.

It is just such cases, however, which are among the most difficult to diagnosticate, and therefore I wish to speak of those which present greater difficulties in the way of diagnosis than are seen in the ease of the boy before us.

FREQUENCY OF OCCURRENCE.

I will first say that typhoid fever is not rare either in infancy or childhood. It appears that, in the same degree that we learn more of the morbid anatomy of diseases, the number of diseases increases which can be diagnosticated. It is a peculiar fact, also, that it is especially the infectious diseases which have been heretofore presumed to be rare in infancy and in childhood. I will, for instance, remind you of the fact that only a few years ago it was taken almost as an axiom that acute articular rheumatism was of rare occurrence in childhood and equally rare in infancy. I believe I have settled that point in infantile pathology, and have proved, in an essay published some time ago (Seguin's Amer. Clin. Lect., Vol. 1, No. 2), that acute articular rheumatism is of very frequent occurrence in infancy, and is the frequent cause of endocarditis in children of any age. The same is true with regard to typhoid fever. In former years the disease was almost unknown in children. There was a time when it was known as infantile remittent fever. It was known that there were children who were sick for a number of weeks, who had slight fever in the afternoon, followed by a remission in the morning, perhaps an intermission, and it was called sometimes intermittent fever and now and then infantile remittent fever. That was a justifiable diagnosis before the pathological anatomy in a large number of the cases was recorded. I need not tell you that you have a very great advantage over former physicians, who did not know that every disease must have an anatomical lesion at its foundation. A little time before I was a student in medicine there were many fevers, so called, such as catarrhal fever, rheumatic fever, nervous fever, etc., although the names were not based upon any anatomical substratum. You will recollect from general lectures upon pathology that it was left for Rokitansky to find the anatomical lesions which always accompanied certain symptoms, and especially with reference to typhoid fever. Only since that time has it been possible to diagnosticate typhoid fever through the anatomical lesions found in the cadaver, and through symptoms corresponding with those anatomical lesions.

SYMPTOMS OF TYPHOID FEVER IN THE ADULT.

I will now repeat what you would expect to find in a case of typhoid fever occurring in the adult, in order to point out what you can expect in the typhoid fever occurring in the young. I shall not enter upon the pathology of typhoid fever, but simply point out the difference between the infantile and the usual adult manifestations of the disease. You would diagnosticate a case of typhoid fever in the adult by a number of different symptoms, of which the principal are the following:—As a rule there are mild chills at the beginning of the disease. Severe chills may be

present at the onset of typhoid fever, but generally only in the beginning of the second week. As a premonitory symptom, then, there is a universal chilliness and a feeling of uncomfortableness. There is a moderate amount of diarrhoea; there is pain upon pressure in the region of the ileo-caecal valve, and gurgling in that locality. There is swelling of the spleen, and in the adult the increase in size may be such that the organ measures four, five, six, or even seven inches in its longitudinal diameter. In the adult there is generally found over the chest and abdomen a roseolous eruption, occurring usually about the sixth or seventh day, sometimes as early as the fifth. The eruption lasts about one week, perhaps a little more, and then gradually disappears. There may be hemorrhages from the bowels in the course of the second or third week of the disease, and the affection runs its entire course in from twenty to twenty-one days. Now and then relapses will set in, which it is not necessary to attribute to serious errors in diet or other external causes. It is in the nature of the disease that relapses should take place. There are always some ulcerations of Peyer's patches, and relapses may be developed in consequence of the absorption of disintegrated material from these ulcerated surfaces. Such relapses may occur, so that the patient will pass through two courses of typhoid fever within six weeks. Even a second relapse may occur, and usually the last relapse is less severe than the others. I can state that I have seen a case in which three relapses occurred, the patient passing through four typhoid fevers, and making a good recovery; he still lives in this city. In such cases where you do have opportunities to make post-mortem examinations, you will find that the ulcerations are not limited by the ileo-caecal valve, but they will be found all along the colon, and frequently down in the rectum. Such a case I saw in the body of a lady who had a severe hemorrhage from the bowels on the ninth day of her typhoid fever. The exhaustion was so great that she was pulseless; but her life was saved by transfusion of blood. Forty-one days afterward she died; that is, on the fiftieth day from the beginning of the disease.

In that case I found the original ulcerations partly healed, some entirely covered with newly-formed tissue, and others newly formed low down in the rectum.

Let me add a few words with reference to the *temperature* in a case of typhoid fever occurring in the adult. In severe cases, and in some epidemics, the course which the temperature pursues is quite characteristic. There is a gradual increase in the morning and evening temperature, which has been said to be characteristic of typhoid fever. I think you will find, when you come to practise, that the picture with reference to regularity in the temperature curve in typhoid fever has been overdrawn. You will not find it as it has been represented. I believe that among twenty cases of typhoid fever fifteen will be found which do not yield the regularity in the temperature curve to be expected from the statements made in textbooks, and in articles in medical journals. In some epidemics of typhoid fever the temperature is quite peculiar, and the diagnosis can sometimes be made from it alone, but such instances are rare. During the present autumn I have seen a large number of cases of typhoid fever, and of those there has been scarcely a single one which could be diagnosed according to the books; that is, from the diarrhoea, or from the roseola, or from the enlarged spleen, and such symptoms as are frequently found

associated in cases of typhoid fever. I have seen cases in which there were first and second relapses, and even in those the temperature of the primary attack did not exhibit the regular curve mentioned in the books. I have now and then seen a case in which the morning temperature has been higher than that of the evening, in addition to other irregularities which were present. I make mention of these facts, because I do not wish you to leave the college or the hospital with the feeling that you can always diagnose a case of typhoid fever simply by the temperature curve of the first week. You will be obliged to rely upon the bearing of all the symptoms in such cases. For there are a number of cases, even among adults, in which you can reach a diagnosis only by exclusion, being compelled to exclude meningitis, pneumonia, enteritis, etc.

SYMPTOMS OF TYPHOID FEVER IN CHILDREN.

Now let us see what these symptoms amount to in a child; and I will first speak of the mildest cases, which are by no means rare. You will see a child, perhaps one, two, three, four, five, six years of age, in whom simple changes are found by the attendants something like the following. It is noticed that in the afternoon the child becomes restless, perhaps is slightly flushed about the face; has a slight perspiration now and then, and from the appearance of the face it may be inferred that there is a little headache; perhaps that is all, except that the child wants to drink considerably in the afternoon. The next morning the baby seems to be all right, but in the afternoon the same symptoms return, and so the case goes on for a week. Finally, the parents become accustomed to such a trifling sickness, wait another week or two, and the child again begins to eat, and soon is completely well. Such cases are not very infrequent. Parents of a more careful type call a physician when the child has such symptoms, and when he takes the temperature it will be found in the afternoon as high as perhaps 102° or 103° F. If such a child is seen in the morning, when it is apparently perfectly well, the temperature instead of being 100° in the rectum, will perhaps be 100½° or 101° F. As you watch such a case from day to day it may be found that there is no special increase in the temperature of the body, and the child recovers, as a rule, within two or three weeks. Sometimes the disease pursues a more irregular course, and the child may be sick for four or six weeks.

In other cases you will find that the uneasiness and uncomfortable feeling is complicated by a little diarrhoea at some time in the progress of the disease. It may be called a teething diarrhoea, or a diarrhoea from a cold, or it may be explained in various ways by the mother or the neighbors. Occasionally there is a little pain over the abdomen, though rarely, however, and now and then there will be some slight tympanites, but as a rule there is none.

Occasionally you will find slight *enlargement of the spleen*, but more frequently there will not be found any increase in the area of percussion dulness over the spleen in a case of typhoid fever in a child, and for two reasons. In the first place, the spleen, in many cases, does not increase in size; and in the second place, it is difficult to find the spleen in a child. The chest is so short, the abdomen reaches high up, and the diaphragm does not make much of an excursion in the respiratory movements. Again, the intestines may crowd upward on the left side so that a tympanitic percussion note will be obtained all the way beyond the line of the diaphragm. It is sometimes impossible to percuss the normal spleen in a

child, and in the same way it is difficult to find the spleen in many cases of typhoid fever occurring in children.

The *pulmonary symptoms*, which are almost invariably present in typhoid fever occurring in the adult, may be and frequently are absent in the child.

There may be *bronchial catarrh*, but it is not at all necessary.

Such children do not wish to lie in bed, and with such mild symptoms they will be found up and about the room, or perhaps lying on the lounge in the afternoon.

The fact is, that the principal anatomical lesions which are found in typhoid fever in the adult are in part or entirely absent in typhoid fever as it occurs in the child.

There may be a little swelling of the spleen, slight tympanites, there may be a few ulcers in Peyer's patches, there may be a few spots of roseola, a slight diarrhoea, or every one of these symptoms may be absent.

Therefore, in a number of cases you will be obliged to make very accurate observations regarding the morning and the evening temperature, and carefully study the entire child, in order that you may be able to say that there is positively no pneumonia, meningitis, enteritis, and no acute articular rheumatism. Then, as we do know that typhoid fever may pursue a slow course and extend over three, four, five, or six weeks, you may say that it is a case of typhoid fever.

I have stated that the disease is found in the young, and found very frequently. It is even found in the new-born; but such cases are rare exceptions. I believe that the entire number of cases of typhoid fever reported as occurring in the new-born is only four or five, and to those I can add one which I have never reported. It was the case of a child born of a primiparous woman in the upper part of this city, which at that time was not so populous as it is now. The house was in a bad condition, and the mother was very poorly at the time of her confinement. The baby was taken with a regular fever which could not be easily explained, but which in the beginning of the second week I made out to be typhoid fever. The baby died on the sixteenth day, and at post-mortem examination I found the spleen slightly increased in size, and there was slight ulceration of Peyer's patches, thus proving that the case was one of typhoid fever.

Why is it that the symptoms of typhoid fever are so slight in the child, when certainly children show less resistance to a great many other diseases than is offered to the same diseases by adults? I believe the chief cause must be looked for in the fact that the principal anatomical lesion in typhoid fever cannot be developed to such an extent in the child as in the adult. The glands in the intestinal tract and throughout the entire body are but slightly developed in infants. Peyer's patches are but small and few in number, and sometimes you will find no more than six or seven altogether. Their physiological function appears to be very limited, and thus it is that the pathological changes taking place in them are but slight. For pathological development is, as a rule, only an overstrained development of physiological function, and therefore I say that as Peyer's patches are but slightly developed anatomically and physiologically, they give rise to but slight inflammation, ulceration, etc., in the child.

There is another theory which has been advanced by one of the best men among us, viz., by Gerhard. His opinion is the following: That the poison of typhoid fever is introduced into the body through the respiratory organs or through the diges-

tive organs; that it is introduced through the respiratory organs in many cases, but in more cases through the digestive organs, especially by means of drinking-water. Now, babies and little children drink but little water, and that little has generally been subjected to boiling, etc., and is in such condition that the infecting material is destroyed. Thus infection in infants is less serious than in adults, and in his opinion this is the reason why typhoid fever is so mild in children.

(To be continued.)

Original Communications.

THREE CASES OF REMOVAL OF THE OS CALCEI.

BY CHARLES T. POORE, M.D.,

SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, AND TO CHARITY HOSPITAL, NEW YORK.

CASE I.—Fanny M., aged 3 years, was admitted into St. Mary's Hospital, July 26, 1874, with a large sinus, from which there was a considerable discharge of pus, situated on the dorsal surface of right foot over the upper border of the cuboid bone. There was also disease of the first metacarpal bone of left hand. The child was unhealthy-looking, having that look so characteristic of the so-called strumous diathesis.

September 24.—Patient was etherized, and an incision made on the dorsal aspect of the foot, so as to pass through the sinus in that situation, and several small pieces of loose bone were removed. It was then found that the disease was confined to the os calcis, and a considerable portion of that bone was removed through the opening made. The portion of the bone left seemed hard, and was supposed to be healthy. The wound was stuffed with lint, and the foot placed on a rectangular splint. After some time the incision closed, except a sinus which continued to discharge pus, and through which diseased bone could still be felt.

In January, 1875, some more diseased bone was removed, the old incision being reopened.

In April the foot was no better than at time of admission. Patient was again put under ether, and an incision made down to the bone on the plantar surface of the foot from a point corresponding to the insertion of the tendo Achillis forward, so as to give sufficient room for the removal of the whole os calcis. This was easily done. The cavity thus left was stuffed with lint, and the foot placed on a splint. The wound was kept well filled with lint, so that it should heal from the bottom. The wound gradually closed, and patient regained good use of her foot, so that she walked without any limp. She was seen more than a year after she left the hospital, and the foot had continued in good condition. There was some flattening of the plantar arch, and some depression below the external malleolus. Careful examination failed to detect any new formation of bone.

CASE II.—Michael D., aged 3½ years, was admitted into St. Mary's Hospital January 9, 1879, with disease of the os calcis of right foot of some duration. The bone has been gonged twice previous to his admission into St. Mary's. He is a healthy-looking boy. Nothing can be obtained as to the history of his trouble. His parents are healthy. There is a sinus on the external aspect of right foot over the anterior portion

of the os calcis, through which diseased bone can be felt.

February 1st.—He was etherized, and the old incision on the external aspect of the foot reopened, and the tissues separated from the lateral surface of the bone, when a cloaca was found leading into a cavity in the os calcis, in which there was a loose piece of bone about the size of a small filbert. The walls of this cavity were smooth and hard, evidently composed of sclerosed bone. The wound was washed out with a solution of chloride of zinc, the cavity stuffed with lint, and the foot placed on a splint. Hemorrhage was controlled by an Esmarch bandage. After discharging profusely for some time the incision closed, the sinus assuming the same appearance that it had before the operation.

May 3d.—Patient was again placed under ether, an Esmarch bandage applied, and, assisted by Dr. Watts, the os calcis was excised in the following manner: An incision was made beginning at a point corresponding with the inner edge of the tendo Achillis, and on a level with the upper border of the tuberosity, outward and forward on to the external aspect of the foot to a point midway between the external malleolus and the proximal end of the fifth metatarsal bone, the incision going down to the bone, and the periosteum easily detached. The bone was removed in pieces, and the periosteum was left almost intact. The cavity was filled with soft granular tissue. The walls were sclerosed, and what remained of the cancellous tissue was diseased. After removing the bandage there was a very free hemorrhage from the inner surface of the periosteum. The external portion of the incision was brought together with silver sutures, leaving an opening behind for drainage. The cavity was washed out with a solution of the chloride of zinc, then stuffed with lint and bandaged, and the foot and leg placed on a posterior splint.

May 5th.—Lint removed and drainage-tube inserted.

May 10th.—Incision all healed, except where the drainage-tube was inserted; discharge moderate.

May 29th.—There are now only two small sinuses; one behind where the drainage-tube had been, and one in the location of the old sinus.

June 10th.—Patient up and about.

September 30th.—There is now a small sinus that discharges a little serous fluid. No exposed bone can be detected. He can walk and run about, makes no complaint of any pain, has good use of his foot, but uses his knee awkwardly. He went out of the hospital to-day. I do not think that there has been any regeneration of bone.

CASE III.—Mamie S., aged 7 years, was admitted into St. Mary's Hospital January 10, 1879, with disease of the os calcis of right foot. Her father died of consumption, her mother is healthy, but her sister and brother look pale and unhealthy.

Three months ago she began to complain of pain in the heel of right foot, which soon began to swell. Five weeks ago the abscess opened on the back of the heel, and has continued to discharge ever since. At date of admission there was a sinus discharging a small quantity of pus situated on the posterior part of the heel, and through which a probe passed; detected diseased bone.

Patient was a pale, unhealthy-looking child.

March 15th.—Patient was to-day etherized, and, assisted by Dr. Watts, the os calcis was removed in the same manner as in the last case. The bone was found to be diseased throughout. The periosteum was easily separated from the bone. Hemorrhage was controlled by an Esmarch bandage. On removing

this there was but little hemorrhage, and only one small vessel had to be ligated. The cavity was washed out with a solution of chloride of zinc. The lateral portion of the incision was brought together with silver sutures, leaving the posterior portion of the wound open for drainage; through this a drainage-tube was passed, and the wound covered with a few layers of carbolized gauze, and over this cotton and a bandage. Limb put into a splint.

March 25th.—Since operation patient has done well. For a day or so after the operation temperature was elevated, but it is now perfectly normal. There is considerable discharge from the cavity of the wound, and there has been some swelling of the foot, but she has suffered no pain.

April 3d.—The line of incision has all closed, except where the drainage-tube is inserted.

May 3d.—Drainage-tube removed, cavity almost filled up, not much discharge. She can bear her weight on the foot, and is walking about.

June 10th.—There is some slight watery discharge from the sinus in the back of the heel. Patient can walk well. Parent removed her to-day from the hospital.

Cases of disease of the os calcis are mentioned by Mr. Hancock where, after gouging or the removal of sequestra, good results have been obtained. Yet, in two of the cases mentioned above, gouging entirely failed to eradicate the disease, and the patients did well only after total resection of the bone. Case No. II., where there was a sequestrum contained in a smooth cavity in the os calcis, would seem to have been a case where the removal of the dead bone should have been followed by a cure; but the sclerosed condition of the surrounding bone and its consequent low state of nutrition, on account of the partial cutting off of its arterial supply, may have been the cause of the failure to reproduce bone, and a no small element in the persistence of the disease. Gouging, or partial excisions of this bone for disease, is looked upon, by those who have had much experience in the surgery of the foot, as not apt to be followed by good results.

Most writers on excision of the os calcis advocate two incisions, one of which is at right angles to the lateral, and encroaches more or less on the plantar surface of the foot. In Case No. I. the bone was easily removed through an incision confined entirely to this surface; and, although plenty of room was obtained, yet the resulting cicatrix caused a deep depression on the plantar surface which I think a disadvantage. The mode of removal of the bone in the last two cases was that advocated by Mr. Hancock and Mr. Holmes, except that the second incision at right angles to the first on to the plantar surface was omitted, and yet plenty of room was obtained. In all the cases the tendo Achillis became blended with the cicatricial tissue, and thus gained a firm point of insertion. There was some flattening of the heel in all of these cases, but this did not interfere with the usefulness of the foot.

THE DOCTORS IN MEMPHIS.—In 1878 all the homœopaths, four in number, ran away when the plague came. Of the forty-six regulars, ten followed in their wake; of the thirty-six who remained, twenty-eight were attacked with the fever and fourteen died. Eight had already had the disease and were not attacked at all, though on duty day and night. The facts corroborate the belief that one attack gives immunity from a second.

SLOW UNION OF FRACTURE OF LEG.

By Prof. GEORGE E. POST, M.D.,

BEIRUT, SYRIA.

ON page 17, No. 452 of the *MEDICAL RECORD*, is the report of a case of non-union of fracture of the tibia of twelve years' standing. Reading this case prompts me to report a case of slow union.

John Dwyer, a seaman in the British navy, 24 years old, fell from a horse while drunk, and broke both bones of his right leg at its middle. Two years previous a spar had fallen on the tibia of the same leg, and he appears to have had periostitis without suppuration. He remained for two months in hospital, but was at last discharged cured.

The fracture being simple, was at once put up in a plaster splint, and left for five weeks. On taking it down there was almost as much mobility as at the time of the fracture, and very little callus about the broken ends of the bone. I immediately reset the leg in a firm plaster dressing, which I carried half up the thigh. In ten days from the time of the application of the second splint I was obliged to remove it on account of the intolerable itching, which led the patient to believe that it was infested by innumerable bedbugs. None were found; but the skin of the leg, from the knee to the ankle, was pierced with small punched-out ulcers, giving the limb the aspect of a stick of timber bored by teredos. This made it quite out of the question to attempt the restoration of the plaster apparatus. I applied Cline's splints to the internal and external aspects of the leg, and dressed the limb with zinc ointment. By removing the splints twice daily, and very carefully avoiding all motion of the fragments, the leg was kept tolerably clean. The ulcers, however, did not heal entirely until three months later, and in the meantime the fracture slowly consolidated, with very little callus around the broken ends. It was six months from the time of the injury before he was able to begin to walk. Although there is no angular displacement, and the fracture was quite transverse, and no overriding of the fragments occurred, there is a shortening of half an inch, which I can only explain by the absorption of a portion of the free extremities of the fragments before and during the process of union, such as takes place in the neck of the thigh bone and the humerus in some cases.

The patient finally obtained a useful limb, and the halt in his gait has been corrected by the use of a high-heeled shoe. He expects to return to active duty in the navy.

A CASE OF DISLOCATION OF THE PATELLA UPON ITS AXIS.

VERTICAL DISLOCATION AND A CASE OF DISLOCATION OF THE THIGH DOWNWARD AND FORWARD INTO THE FORAMEN THYROIDÆUM, IN A CHILD THREE YEARS AND ONE MONTH.

By ERSKINE MASON, M.D.

THESE two rare cases, as to character and age of one of the patients, having lately fallen under my care, I deem them worthy of being placed upon record, as so few of a similar nature have been reported.

DISLOCATION OF THE RIGHT PATELLA UPON ITS AXIS.

While making my visit at the Roosevelt Hospital on the afternoon of Sept. 4, 1879, a strong muscular man, aged 27 years, blacksmith by occupation, was brought

into the ward, who had met with this accident about an hour before admission. While shoeing a horse (the hind leg of the animal being between his knees) the horse became restive, and, almost falling, pressed his leg heavily upon the under edge of the right patella, thus producing the dislocation. Upon entering the hospital he complained of great pain in the knee, especially when the bone was touched. The limb was extended, and the patella, with its anterior surface outward and in a perfectly vertical position, was found firmly locked in the inter-condyloid fossa. The tendon of the quadriceps was twisted upon itself, prominent, and felt like the ligamentum patella, which was also raised and very tense.

All examination being exceedingly painful, he was at once placed under ether, when I thoroughly examined the parts and proceeded to the reduction of the bone. First I flexed, and then, while extending the leg, made pressure upon the patella; this failed. Second attempt, I flexed the leg rapidly, and then strongly extended the leg; this seemed to unlock the bone a little from its fastening, but lateral pressure failed to reduce it; then, while extending the limb, I firmly crowded down the rectus, and with the assistance of the other hand and that of Dr. Watts, pressure being made against the bone, it readily passed into place. The chief aid in reduction, in my opinion, was the crowding down of the rectus. The after-treatment consisted of the application of a posterior splint and an ice-bag on the limb for twenty-four hours. No ill-consequences followed, and he left the hospital on the twelfth day with perfect use of the joint.

DISLOCATION OF THE RIGHT THIGH DOWNWARD AND FORWARD INTO THE FORAMEN THYROIDÆUM, IN A BOY AGED THREE YEARS AND ONE MONTH.

This patient I saw in consultation with Dr. Geo. H. Basly. The manner in which this injury occurred could not be satisfactorily accounted for. All the parents could state was, that while in the country one afternoon he was playing in a room with some trunks and boxes, and, as the child states, he fell. He complained of no pain, and the only thing that attracted the attention of the parents was the manner in which the child stood and walked. A glance at the child in the erect position revealed at once the character of the trouble which the doctor told me I was to see. The limb was abducted, thigh slightly flexed, and the foot turned a little outward, while there was a depression where the prominence of the trochanter should be seen, and the head of the bone was felt in its abnormal position. By measurement the limb was nearly an inch longer than the other. The child complained of no pain except when the head of the bone was pressed upon. He could run about the room and go up and down stairs without much difficulty, and seemed rather amused at the position of his limb and the peculiar gait when walking.

On September 17, 1879, the fourth day of the injury, ether having been given (up to the point only of primary anesthesia), I flexed the thigh at a right angle to the pelvis, slightly abducted and gently rotated inward; adducted, and the head of the bone passed at once into the acetabulum. The whole operation did not consume more than a minute. These manipulations are those laid down by Bigelow in his work on the Hip; and in this connection I might say that in two other cases of dislocation upon the dorsum in adults I have effected ready reduction by the method he advocates; while in one case of dislocation upon the pubes, reported in the *RECORD*, April 8, 1876, various manipulations were resorted to before reduction

was accomplished. After a somewhat extended research through the literature of dislocations of the thigh, this is the youngest person with dislocation into the thyroid foramen, with the exception of the one reported, of an infant six months old, by Powdrell, in the *Lancet* for May 16, 1879, that I have found recorded.

Reports of Hospitals.

NEW YORK HOSPITAL.

SWELLING OF COSTO-STERNAL JOINTS—EFFECT OF SALICYLATE OF SODA.

(Reported by T. ROLAND CHAMBERS, M.D., late House-Physician.)

HELEN SIMPSON, *et. 55.* History of intemperance and rheumatism. Last rheumatic attack eight years ago. Cough, with frothy sputa, for nine months. Two months ago this cough became very painful. At that time tumors appeared at edge of sternum, which have steadily increased in size and sensitiveness. During the past week there has been persistent nausea and vomiting, and no sleep for three days.

On admission, patient was much emaciated. Features of face show that she has been, and is suffering intense agony. Every respiratory effort is painful, and motion of the right knee or either ankle elicits a cry. Temperature, 103.5° F.; respiration, 35; pulse, 125. On the right side, at the articulation of second costal cartilage with sternum, is a prominent circumscribed swelling, tense and fluctuating, about the size of a hickory-nut. It crepitates with each respiration. The cartilage is drawn in with inspiration, and passes out beyond sternum with expiration. The same kind of tumor and similar symptoms exist at third and fourth costo-sternal articulations, same side. The aggravation of symptoms during the past week is accounted for by the pneumonia which undoubtedly exists in both upper lobes of right lung. There are heart murmurs.

The points of interest are: the location of the swellings; the fact that two ribs are, as it were, floating in a fluid, and are drawn in with inspiration, and pushed out with expiration; that after four days' administration of salicylate of soda, sixty centigrammes every two hours at first, and less frequently later, the swellings almost entirely disappeared, as well as the luxation of the cartilages. The patient died, however, and the autopsy revealed gray hepatization of both upper lobes, right lung; atheroma in heart and vessels; general parenchymatous and interstitial changes in the various organs. The opposed surfaces of joints, where the swellings had been, were found to be the seat of calcareous degeneration.

The right kidney was found with its long axis lying transversely.

THREE CASES OF SUSPECTED ANEURISM.

August Müller, *et. 46,* sailor; died April 6th. Complained of pain, cough, dyspnoea, anorexia, aphonia, loss of health and strength. Examination reveals slight paralysis of left vocal cord, visible pulsation of arteries in neck, systolic bruit distinct all over chest; and the finger, pushed in over the episternal notch, felt the aneurism itself. The left radial is very much smaller than the opposite pulse, and the sphygmographic trace made the descent of the left to be straight, while the right was a broken line.

The diagnosis here seemed plain—a large aneurism of the arch sufficient to interfere with the left recurrent nerve. The man died suddenly, and autopsy revealed a very “moderate” dilatation of the upper part of the arch; but the opening of the left subclavian artery was only about one-tenth the diameter of the right. The interior surface of the aorta was very rough (atheromatous).

William Proctor, *et. 32,* sailor; died June 2d. Complained of pain, cough, dyspnoea, and anorexia. Examination revealed a loud systolic bruit all over the chest and down the spine. In addition, a double murmur at apex. This man's chest had considerable dullness, which was not marked in the case of Müller. The right pulse here had a single break in the descent, while the left had two breaks; both had same length of ascent according to the sphygmograph. To the finger, the right seemed to be slightly smaller than the left pulse.

Dr. McLane's diagnosis was hypertrophy and dilatation of heart and *no* aneurism; but a number of others, after careful examination, thought there was a small aneurism, possibly of the first part of the arch. Autopsy showed Dr. McLane's diagnosis to be correct. The valves were atheromatous, and if there was any dilatation of the aorta, it was so slight as not to be called abnormal.

Thomas Farrell, *et. 35,* huckster; died September 24th. This man's figure was like an inverted L. The cervical spine was at right angles with the lumbar. The house-physician admitted and discharged the patient as a case of caries of the spine. There was double kyphosis at seventh cervical and ninth dorsal regions. The man's condition was such that an extensive examination was impossible. He had crowing inspiration and a peculiar high-pitched tone of voice, as if there was pressure on the trachea somewhere. He had cough with tenacious sputa, which at times, and especially latterly, contained blood and small, dark blood-clots. The physical signs pertaining to the circulatory apparatus were masked by the peculiar shape of the chest. The abdominal aorta could not be gotten at by the stethoscope. It was difficult to reconcile his frequent dyspnoeas (controlled by a hypodermic injection of morphia) with such a steadily progressing disease as caries. There was nothing noted in the radial pulses. Finally, the man died in an attack of dyspnoea, and blood came from the mouth, then thought to be from a bitten tongue; but post-mortem examination shed a light on everything except the caries of the spine. The family objected to having his unsymmetrical curve destroyed, and we were deprived its thorough study, but they could not prevent our seeing a large clot protruding through an opening in the aorta, at a point just below the opening of the left subclavian artery. The opening was large enough to admit a hickory-nut, and it communicated with the sac of an aneurism large enough to hold two walnuts. It contained a black clot commencing to organize toward its deeper part, where it lay upon, and had eroded three rings of the trachea, and had opened into its calibre in two places between the rings. The mucous membrane for a considerable area was much congested, and the rings were calcareous.

DR. OLIVER WENDELL HOLMES has recently passed his seventieth birthday; Dr. Willard Parker recently began his eightieth year. Both are still vigorous men, and Dr. Holmes is expected soon to publish another volume.

PENNSYLVANIA HOSPITAL, PHILA-
DELPHIA.NOTES OF PRACTICE AND PECULIARITIES OF TREAT-
MENT.

(Prepared for THE MEDICAL RECORD.)

PATULOUS AORTIC VALVE IN CHRONIC BRIGHT'S DIS-
EASE.

The patient was found lying unconscious in the street. When brought into the hospital his pupils were contracted and his breathing stertorous. The radial arteries were very tortuous. One-sixth of the bulk of the urine was found to consist of albumen. The feces were passed involuntarily.

Immediately upon admission the man was given grt. ij. of croton oil in a teaspoonful of olive oil, and a dose of the following prescription:

R. Spts. chloroformi (B. P.).....gtt. xxx.
Acid. benzoici.....gr. vj.
Potas. bicarb.....gr. xxx. M.
S. Drops ten every two hours in water.

For sustenance the patient took three pints of milk and one pint of beef-tea, together with f 3 j. of alcohol, the milk and beef-tea being given in small quantities at short intervals.

Atropia was injected into the eyeball, but did not dilate the pupil sufficiently to enable the visiting physician to examine the eye-ground with the ophthalmoscope.

When examined carefully on the day after admission, the right side of the patient's mouth was found to be paralyzed. So, too, were the right arm and right leg—the leg less so than the arm. The man was still dull and inattentive. His respirations were forty-four to the minute, and his pulse 116. The radial arteries wound along like worms, and pulsated visibly from the elbows to the wrists. Another curious fact in connection with the case was the presence of rounded, hard tumors on the back of his elbows and over his phalangeo-metacarpal joints. One of these tumors was opened, and a very thick, creamy matter escaped, which yielded crystals of tyrosin under the microscope. It was impossible at that time to detect any murmur of aortic regurgitation.

In endeavoring to reach a correct diagnosis in the case, the visiting physician was led at first to regard the case as one of opium-poisoning, owing to the marked contraction of the pupils; but this view of the case was invalidated by the facts of paralysis and stertorous breathing. It was finally determined that the case was one of chronic Bright's disease, and the opinion unhesitatingly advanced that further examination would reveal the presence of tube-casts, and that when the more violent symptoms had subsided a regurgitant cardiac murmur would be heard. Mention was made of the statement advanced by Walsh, of London, viz., that the tortuousness of the arteries present in the case is only present in patulous aortic orifice and coarctation of the aorta.

Subsequent events proved this diagnosis to be the correct one.

The patient's comatose condition, dependent upon the uræmic poisoning, was found to yield very markedly to the following prescription, recommended by Dr. George Johnson, of London, viz.:

R. Scammonii resinæ.....gr. v.
Potassii bitart.....gr. xx.
Zingiberis.....gr. viij. M.
S. To be administered when needed.

OPHTHALMIA NEONATORUM.

A solution of nitrate of silver (three-quarters of a grain to the ounce) is injected under the lids twice a day.

For the lids themselves the following is usually employed:

R. Sodæ boratis.....gr. xij.
Zinci sulphatis.....gr. j.
Aquæ camphoræ.....f ʒ j.
Aquæ destillatæ.....f ʒ j.

M.

S. To be applied to the lids two or three times a day.

A plan of treatment highly recommended by Mr. Dickson, of London, viz., the injection between the lids every half-hour of a solution of alum (from five to eight grains to the ounce), the strength of the solution to be gradually diminished as the case gets better, has also been tried with very gratifying results.

THREE INTERESTING CASES OF SPINAL DISEASE.

CASE I.—The patient, a sailor, was brought into the hospital with a history of a fall of thirty feet from the rigging of his ship while at sea. He fell partly on his head and partly on his back. When picked up he was unconscious, and remained so for fifteen minutes. Upon regaining consciousness he found that his right arm and leg were entirely paralyzed, and the left arm almost entirely so. The patient received no treatment whatever while at sea.

Since admission the patient had been carefully examined and found to be free from any disease of his heart, lungs, liver, or kidneys. The ophthalmoscope revealed a slight optic neuritis, but not enough to indicate any serious disease of the brain. When he walked he carried his head somewhat forward. The effort to straighten the head gave the patient pain. At the point of junction of the cervical and dorsal spine some thickening and induration were found. The right arm had not entirely recovered its power. He was unable either to extend or close the fingers of that hand. There was some atrophy of the muscles of that hand. The circulation of the same limb was also found to be very defective. The left hand and arm exhibited the same conditions, but to a lesser degree than the right arm. The man's walk was peculiar. The right leg was stiff and trembled when he walked. Upon stripping the limb the feet were found to be abnormally extended. Attempts to bring the foot up to a right angle were attended with great trembling of the member and marked tension of the tendo Achillis. The tendon reflex of the patella of both legs was most marked. There was no decided impairment of the sensation of either touch or pain in the feet. Contraction of the muscles under the faradic current was slightly impaired in both legs and arms. Now and then trembling could be produced by pressure upon the lower part of the spinal column.

In debating the case, two difficulties were encountered. 1st. In connection with the nature of the original injury; and second, as regarded the present nature of the disease. Concerning the first point, concussion of the spine seemed hardly possible, since it could not account for the paralysis of the muscles of three extremities. It seemed more probably to have been a case of apoplexy of the cord. It was concluded, however, that the effusion of blood could not have been a large one, since there was no paralysis of the left leg, no urinary difficulty, and no pronounced tendency to the formation of bed-sores.

Concerning the second point to be decided, it was thought that the symptoms then present pointed conclusively to an involvement of the lateral columns. This opinion was strengthened by the presence of spastic muscular contractions. The absence of *anæsthesia* proved that the posterior columns could not be seriously affected, and the absence of *analgesia* seemed to show the same to be true of the gray matter. It was thought that simple concussion of the spine was sufficient to produce inflammation of the lateral columns.

As soon as the patient entered the wards a blister was applied to the seat of induration in the back, and bromide of potassium administered internally. When it was seen that inflammation of the cord existed, one-sixteenth of a grain of the bichloride of mercury was ordered four times a day. Later he was put upon gr. x. of potassium iodide thrice daily, which dose was subsequently doubled. It was remarked, in connection with the early history of the case, that *ergot* and *belladonna* would have been the proper remedies to employ immediately upon the reception of the original injury.

For the future occasional blisters were ordered and rest was enjoined. *Strychnia* and electricity were regarded as injurious.

CASE II.—A farmer, with a good family history, who had spent a day in very hard work and during the following night had been much exposed to cold and wet. This imprudence, which took place eleven months before his admission to the hospital, was followed by loss of power in the lower extremities and complete paralysis of the bladder.

For two or three months after this period the patient had shooting pains in his legs and was much troubled with nocturnal delirium.

The man was carefully examined after his admission, and found to be suffering from marked *paraplegia* without involvement of the rectum or bladder. The strong faradic current elicited no response whatever in either leg, except from the flexors of one of the big toes; using the continued current the same results were observed.

The case was regarded as a typical one of acute spinal paralysis—a rare form of disease in the adult—in which the lesion was in the anterior horns of the spinal cord. The location of the lesion was thought to account for the entire loss of electro-muscular contractility, while sensation was so little impaired. It was also thought to account for the absence of rectal and vesical difficulties and of bed-sores.

CASE III.—A shoemaker, who stated that his troubles dated back to an attack of rheumatism in his legs. This rheumatic attack lasted about three weeks. Pains in the back and legs were associated with the rheumatism.

When admitted to the hospital the man complained greatly of pains in the limbs and back, and of loss of power in the lower extremities. He still walked with difficulty and pain, but the local tenderness and discoloration had gone. It was difficult to decide whether the pains complained of were due to the rheumatism in the extremities. It was concluded that they were not. The man improved very rapidly under the use of the iodide of potassium and *ergot*, and was discharged entirely cured, as it was supposed. Ten days afterward, however, he was again admitted. Upon questioning him closely it was discovered that he had spent all the time since his discharge in walking about the city in search of employment.

After his return to the wards he began to lose power in his legs steadily. The pains in his back and legs returned, and he spoke of a feeling of great con-

striction around his waist. Still later the legs began to atrophy, and still the loss of power remained. The electro-muscular contractility was very much diminished, while the sensibility seemed to be slightly deficient in both of the lower limbs. The capillary circulation was very defective, the blood circulating very irregularly in the superficial tissues. Reflex sensibility still remained intact. The muscular sensibility had gradually increased.

It was concluded very early in the progress of this case that it was one of rheumatic paralysis of the cord, or rheumatic spinal myelitis.

Anatomically speaking, it was pointed out that the lesions in Cases II. and III. were the same, both being located in the anterior horns, but in Case II. there was no rheumatism, and the spinal paralysis came on at once; while in Case III. the rheumatic origin was plain, and the spinal complications came on at a later period. The treatment of Case III. was by gr. xv. of the iodide of potassium thrice daily, with a little iron and locally friction.

In the discussion of Cases II. and III. some very interesting points were brought out. Particular attention was directed to the rapid atrophy of the muscles of the lower extremities in both of the cases. This atrophy was emphasized as being the most typical and constant symptom of this class of affections, the rapidity with which this atrophy progresses being in proportion to the acuteness and persistency of the attack.

Another fact, to which particular attention was directed, was that this atrophy, as a general rule, is not permanent. In cases where recovery has been more or less complete, the limbs are found to have regained, to a greater or less degree, their normal shape and power, the completeness of the return of the limb to its normal shape being dependent, of course, upon the completeness of the patient's convalescence. Complete restoration to power and health was regarded as rare. It was argued that the real extent of the damage done depended upon the number of trophic cells which had been destroyed. If enough of them remained intact, when the morbid process had ceased, to minister sufficiently to the supply and nourishment of the atrophied muscles, it was easy to restore them for a time lost functions by means of proper nerve-food, friction and electricity in the shape of galvanism, and in the later stages by the hypodermic use of *strychnia*.

The question arising as to whether the tape-measure was the only means of judging definitely of the condition of the affected muscles, it was pointed out that when it was found upon trial that the faradic current when applied to the affected muscles began to give better results, and when the muscles began to respond and contract, though feebly, it might be accepted as a sure sign of returning health, for it proved conclusively that the muscles were becoming more active, and that the paralysis had reached its height.

It was thought that the same conclusion could not be drawn from the use of the continuous current, the muscles responding to this current so soon that it could not be regarded as any gauge at all.

Attention was called to the facts of the entire absence of rectal and vesical paralysis and of bed-sores in Cases II. and III.

In one point it was shown that these two cases had not been typical ones of their kind, viz.: in so far as the reflex nervous functions had not been in the least impaired in either case.

The treatment was limned out as having consisted at first of local bloodletting in the neighborhood of

the spine, occasional purging, and large and continuous doses of ergot. This at first; later the indications were met by large doses of the iodide of potassium, and by the application of systematic friction to the legs. Later still, it was thought that small doses of strychnia should be administered hypodermically, and when muscular motion returned, that the faradic current should be employed.

ANTEFLEXION OF THE UTERUS.

The patient was a servant-girl, twenty-seven years of age, with a history of menstrual irregularities extending through a period of seven years. Accompanying the flow there had been occasional suprapubic pain. Six months before her admission to the hospital this pain had become constant and she had been compelled to give up all work. She was obliged to pass her water twenty or thirty times a day. The urine was examined, and found to be entirely normal in all respects.

Vaginal examination showed the uterus to be a little lower than natural; the finger encountering the fundus in the anterior cul-de-sac. Together with this anteflexion there was some catarrh of the bladder, while the woman was anæmic and hysterical, and suffered greatly from constipation.

It was concluded that the first thing to do was to build up the woman's general health. Rest in bed was enjoined; thrice a day she took gr. iv. of the ammonio-citrate of iron with gentian, and the following prescription was employed, viz.:

R. Magnesii sulphat. ʒvj.
 Acid. sulph. dil. ʒij.
 Ferri sulph. gr. xij.
 Quiniæ sulph. gr. xij.
 Syrupæ zingiberis. fʒj.
 Aquæ q. s. ad. fʒvj.

M.

S. A tablespoonful in ice-water thrice daily.

To cure the anteflexion, instead of introducing a pessary, it was determined to persuade the woman to teach her bladder to hold gradually more and more urine. It was reasoned that when the bladder could hold twelve ounces, the anteflexion would be largely reduced.

Progress of Medical Science.

A NEW METHOD OF PREVENTING STRANGURY FROM THE USE OF CANTHARIDES.—M. Guyot-Dannezy, of Bordeaux, recommends a mixture of cantharides with carbonate or bicarbonate of soda for vesicating plasters. He uses equal parts of soda and powdered cantharides, strews the mixture on adhesive plaster, presses on it with the hand until the powder adheres to the plaster, and then covers it with oiled paper. Vesication is produced as rapidly and as certainly as when cantharides alone is used, and the experience at Bordeaux seems to show that the soda used in this manner is a much better preventive against the bad effects of the Spanish fly on the bladder, than is camphor.—*Lyon Medical* and *L'Année Médicale*, June, 1879.

RENAL CALCULUS FORMED OF INDIGO.—Dr. Bloxam found, at an autopsy on a woman of middle age, a calculus in the right kidney. It was of a dark-brown color, but covered in parts by a thick, granular, bluish-black coating. Drawn over paper it left a bluish-black mark. Chemical and microscopical ex-

amination showed it to be composed of blood-clot mixed with a little crystallized phosphate of lime, and a large quantity of indigo disposed in the shape of a thick coating. No explanation is given of the significance of the presence of the indigo.—*Revue Médicale*, July 26, 1879.

ON THE FUNCTIONS OF THE TRUE AND ACCESSORY NUCLEI OF THE HYPOGLOSSAL.—In his valuable researches on the bulbar region, M. Duval discovered in addition to the true nucleus of the hypoglossal nerve, which is found in the floor of the fourth ventricle, within and in advance of the nuclei of the mixed nerves, an accessory nucleus situated in a more central portion of the bulb; here with other nuclei, like it, derived from the head of the anterior cornu, it forms a small gray mass known, since the labors of Stilling, Kölliker, etc., as the antero-lateral nucleus. These two nuclei, the true and accessory, are bound together by fibres.

M. Duval has recently had occasion to examine a subject who had suffered from glosso-pharyngeal paralysis, and found that the lesions were not the same in the true and accessory nuclei; in the former no cells remained, in the latter there were still some cells which retained their original form and volume. On investigating the symptoms observed during life, he found that the patient, although unable to pronounce a single word, still retained some use of the tongue: he could suck an orange, and give various exaggerated movements to the organ. M. Duval thinks that it may be inferred from this, that the true nucleus presides over phonation and the accessory nucleus over deglutition.—*La Tribune Médicale*, July 27, 1879.

THE STRUCTURE OF THE BROAD LIGAMENT.—From a large number of pathological and anatomical observations, M. Guérin concludes that phlegmonous inflammation of the broad ligament is, and must be, a rare affection. After pelvic cellulitis, indeed, pus may be found in the broad ligament, but the quantity is small, and this is evidently not the starting-point of the disease. The formation of the ligament is not such as would favor phlegmonous inflammation, it being composed almost entirely of aponeurotic layers; but little cellular tissue is found here, and what is present is dense and firm. All attempts to inject melted tallow or colored water into the substance of the ligament have failed, except when the liquid was simply forced into the subperitoneal tissue; then, indeed, it might be made to appear at the anterior abdominal wall. Most of the symptoms attributed to phlegmonous inflammation of this ligament belong to another affection, which he calls *adeno-phlegmon juxtapubien*, and which has its origin in the neck of the uterus; a lymphangitis first appears, then an inflammation of the lymphatic glands near the horizontal ramus of the pubis, in the neighborhood of the obturator foramen, and of the clitoral ring.—*La France Médicale*, July 16, 1879.

THE TRANSMISSION OF THORACIC SOUNDS TO THE ABDOMEN IN CASES OF ASCITES.—At a recent meeting of the *Académie de Médecine*, Dr. Vidal read a paper on this subject, drawing the following conclusions:

1. The transmission to the abdomen of thoracic murmurs may assist in the diagnosis of beginning ascites.

2. The diminution in the intensity of the transmission of heart sounds, while the respiratory murmurs continue to be distinctly heard in the abdomen, indicates the commencement of hydropericardium.

3. The persistence of the transmitted heart-sounds, while the respiratory sounds are diminished or lost, would indicate the presence of pleuritic effusion.

It would seem from this that the transmission is probably effected by means both of the intestine and of the liquid under certain conditions, with which we are not fully acquainted, but which are similar to those described by MM. De Mussy, Raynaud, and Biocelli, in their works on the transmission of sounds in ægophony, and in certain kinds of pleurisy. The vibrations are transmitted over relatively considerable distances through the gas contained in the intestines, to the liquid, and thence to the ear of the observer.—*Gazette Médicale*, August 9, 1879.

TREATMENT OF CARDIAC DYSPNOEA.—The medicine which has proved most valuable in the experience of Prof. G. Sée, in cases of cardiac dyspnoea, is iodide of potassium. This is especially useful when the dyspnoea is due to a lesion of the heart tissue itself (dilatation or degeneration of the muscle); but it is also of value in valvular lesions. The iodide acts by augmenting, or rather liquefying the bronchial secretions, by which the tubes are rendered more permeable to the air. Iodism may be prevented by associating opium with the salt. Digitalis may be added to the mixture with great advantage, the one relieving the heart, the other the lung.—*Le Concours Médicale*.

POISONOUS PAPER COLLARS.—It has long been a prevalent idea that paper collars contained poisonous ingredients, and were a somewhat dangerous article of toilet. A writer in *The Lancet* has investigated the matter with the following result: he finds that the glazing is done with sulphate of baryta, which is present in large quantity. This salt is very insoluble, and therefore in itself innocuous. It may, however, be combined with other salts which will make it soluble, in which case it would cause great irritation. No arsenic was found at all.

A CASE OF HYPERPYREXIAL TEMPERATURE.—Dr. Graham Steell, of the Manchester Royal Infirmary, reports in *The Lancet* an interesting case of extremely high temperature. The patient was a woman, aged twenty, who first came under treatment for a slight attack of erysipelas. She recovered from this, and, about two months later, began to suffer from retention of urine and cystitis. While treating her for this, she was discovered to have a prolapsed ovary, which occasionally caused her much pain. After being somewhat relieved of these troubles, it was noticed that her temperature became variable, and for the next three months it oscillated between normal and 108°, 112°, and once 113°. She suffered from rigors, during and after which the temperature rose. Its course was somewhat like that of pyæmia, and the fever generally ended in a profuse perspiration. No abscess or evidence of any organic lesion could be found. The patient, until the last part of the illness, did not show any signs of being severely sick. The rises in temperature were of short duration.

The patient finally began to show cerebral and spinal symptoms, and the case looked very much like one of tetanus. Recovery, however, at length took place.

The case, though not completely reported, adds to the evidence in favor of the existence of very high temperatures in the human body.

INFLUENCE OF SUGAR INJECTED INTO THE VEINS ON THE RENAL SECRETION.—In two papers read before the *Académie des Sciences*, in July, MM. Riehet and Moutard Martin reported the results of a series of ex-

periments with the intra-venous injection of sugar. They found that these injections produced almost instantaneously very marked polyuria. The experiments were performed on dogs; a canula was introduced into each ureter of the animal, and the quantitative variations of the urinary secretion were determined by counting the drops that escaped from each canula in the course of a minute, and by measuring the total quantity excreted in a fixed time. The intensity of the polyuria produced is indicated by a few examples. In one case, after the injection of a considerable, but not specified quantity of sugar, a dog excreted 70 c.c. by a single ureter in ten minutes; at that rate about twenty litres would be passed in twenty-four hours by both ureters. In another case, a dog, after having excreted in three hours by the two ureters 28 c.c. of urine, received one intra-venous injection of 44 grammes of sugar dissolved in a small quantity of water, and in the half hour immediately following, it excreted 364 c.c. of urine.

The polyuria appeared very soon, as a rule about a minute and a half after the injection, and when only a small quantity of sugar had been injected; it also disappeared rapidly. The injection of a small quantity of sugar, about 0.50 grammes for 1 kilo. of the weight of the animal (7½ grains for every 2½ pounds), was sufficient to produce marked polyuria, though this was of course not so excessive as in the above examples. The diuresis could not be attributed to the water employed to dissolve the sugar, as injections of even ten times the quantity of water employed in the experiments failed to produce any appreciable augmentation of the urinary secretion. It is scarcely necessary to add that from the second minute after the injection the urine contained very large quantities of sugar. As the urine increased in quantity, it contained proportionately less urea, but this apparent diminution was more than compensated by the augmentation of the urinary secretion; the total quantity of urea excreted was increased as well as the water. Hence, the authors claim that their experiments prove that experimental glycæmia produces not only glycosuria, but also polyuria and azoturia.—*Gazette Méd. de Paris*, Aug. 23, 1879.

TREATMENT OF OBSTINATE SCIATICA BY INJECTIONS OF NITRATE OF SILVER.—M. Damaschino has very frequently employed this method of treatment, which was first recommended by Luton, of Rheims. He injects five drops of a 25 per cent. solution of nitrate of silver into the subcutaneous cellular tissue, usually close to the point of emergence of the affected nerve. Immediate relief from the neuralgic pain is almost invariably obtained. The pain caused by the injection is sometimes very severe, and a small, sharply circumscribed phlegmon forms, which often terminates in suppuration. The pus usually escapes by the orifice left by the needle, but it may be necessary to use the knife. In a case recently treated by M. Damaschino in the hôpital Laennec, only two drops of the nitrate of silver solution were injected. The pain caused by the injection was very acute, but the neuralgia was immediately and permanently cured. A small abscess subsequently formed and had to be freely opened. Several similar cases are reported in the thesis of M. Dureau (Paris, 1877).—*Gazette des Hôpitaux*, Aug. 23, 1879.

THE PHYSIOLOGICAL ACTION OF THE BROMHYDRATE OF CONIA.—The following are the conclusions drawn by M. J. L. Prévost from his experiments on animals with this drug:

1. The paralysis produced by the bromhydrate of

conia is the result of paralysis of the motor nerves, which also lose their excitability.

2. When the circulation is cut off from the hind quarters of a frog, the nerves being left intact, and a dose of from fifteen milligrammes to two centigrammes of the bromhydrate of conia is introduced under the skin of the back, the nerves of the hind legs remain excitable, and these limbs react to excitations applied to the front legs, although the latter are themselves paralyzed by the poison.

3. This effect is rendered more manifest when the frog is poisoned with strychnia; the effects of strychnia and of bromhydrate of conia can then be observed simultaneously in the same animal.

4. The pneumogastric is paralyzed before the other nerves, and its excitability also reappears more promptly when the elimination of the poison takes place.

5. The urinary, salivary, and lacrymal secretions are stimulated by the bromhydrate of conia.

6. The excretion of the poison in the urine has been demonstrated by the experiments. The urine of a cat poisoned by the drug was evaporated to a syrupy consistence in a water-bath, and injected under the skin of several frogs, producing in these animals the characteristic symptoms of poisoning by bromhydrate of conia.

7. The glandular nerves retain their excitability, and secretion can be excited by the application of electricity to them. When the vagi and the nerves of the striated muscles had lost their excitability, electric excitation of the cervical sympathetic and of the tympanico-lingual nerve caused a flow of saliva. Excitation of the peripheral ends of the nerves of the fore leg caused secretion of sweat in the plantar surface of a cat's paw, when electrization of the nerve no longer excited muscular contractions.

8. When warm-blooded animals are poisoned by the bromhydrate of conia, and artificial respiration is kept up, the heart shows the greatest power of resistance to the poison; it is the *ultimum moriens*. It continues to beat even longer than the normal heart after the artificial respiration is discontinued, or when it is removed from the body. In rabbits and cats, direct electrization of the heart by a strong induction current did not produce paralysis, when the poisoning had been pushed to complete loss of excitability of the sciatic nerve. The result was different, however, in the case of a cock. When, in rabbits, the excitability of the sciatic was not entirely destroyed, the heart could be paralyzed by direct electrization, but only after repeated trials.

9. It is very doubtful whether the nerve centres are directly affected by the bromhydrate of conia. The convulsions observed in warm-blooded animals in the last stage of the poisoning are the result of the asphyxia consequent on the paralysis of the mechanical apparatus of respiration. They can be prevented by artificial respiration.

10. The muscular contractility is not diminished by the bromhydrate of conia.—*Archives Générales de Médecine*, September, 1879.

REMOVAL OF AN EXTENSIVE SARCOMA OF THE CHEST.

—At the recent Congress of the Society of German Surgeons at Berlin, Dr. Kolaczek, of Breslau, reported the case of a woman, aged forty-eight years, from whom he had removed an enormous sarcoma, which was situated on the left side of the thoracic wall anteriorly. In removing the tumor it was necessary to resect the third, fourth, fifth, and sixth ribs, with a portion of the costal pleura. The opening left was as

large as the hand; it was covered with a skin flap, a drainage-tube was introduced and brought out through a counter-opening situated posteriorly, and Lister's dressing was applied. The patient recovered. The skin flap adhered to the lung and pericardium, and with each inspiration a depression is produced in which the two fists can be put.—*Le Progrès Médical*, Aug. 30, 1879.

EXTIRPATION OF THE LARYNX AND OF THE PHARYNX.

—At the recent Congress of German Surgeons in Berlin, Professor Langenbeck stated that he had performed the operation of extirpation of the pharynx three times, and that he considered the operation justifiable, although all his cases were unsuccessful. The following are the steps of the operation: First of all, tracheotomy must be performed, and the canula of Trendelenberg introduced; then an incision is carried from the body of the lower jaw, midway between the symphysis and the angle, toward the greater cornu of the hyoid bone, and thence along the anterior border of the sterno-mastoid as far as the upper extremity of the tracheotomy incision. Next, the submaxillary gland must be removed, the lingual artery tied, the stylo-hyoid and the digastric muscles detached from the hyoid bone; the pharynx is then laid bare and can be dissected out, the larynx meanwhile being drawn to the opposite side. The principal dangers to be apprehended are peri-oesophageal phlegmon extending into the mediastinum, and pneumonia from the introduction of foreign bodies into the air-passages.

At the same congress, Professor Billroth stated that six weeks previously he had removed from a woman, aged forty-two years, the pharynx, the cervical portion of the oesophagus, the larynx, a part of the trachea, and all the thyroid gland, for a cancer of the pharynx involving the posterior portion of the larynx. He first performed a preventive tracheotomy, and nine days later proceeded to operate, after introducing the canula tampon of Trendelenburg. The incision was made along the anterior border of the sterno-mastoid. In the course of the operation Professor Billroth found that the tumor extended much further than had been supposed, and as he advanced, step by step, he found himself compelled to remove successively all of the larynx except the epiglottis, the upper rings of the trachea, a large portion of the pharynx, the oesophagus as far as the sternum, and the whole of the thyroid body. An elastic tube was placed in the oesophagus for the introduction of aliment. During the first four weeks the patient did well, the wound gradually contracting, and the elastic tube was then removed in the hope that the pharynx would unite with the lower portion of the oesophagus and form a permanent canal for the passage of food. After the removal of the tube, however, deglutition was accompanied by suffocative attacks and vomiting, and the canal contracted, rendering the passage of bougies necessary. In the sixth week a false passage was made in the peri-oesophageal tissue. Pericarditis and death followed.

Kolaczek, of Breslau, removed a cancer of the posterior wall of the pharynx by a supra-hyoidean pharyngotomy, eight weeks before the congress met. The patient was still living at the date of the report, and was nourished through a tube placed in the oesophageal fistula. Koenig, of Göttingen, and Gussenbauer, of Prague, have also removed cancers of the pharynx, and, like Langenbeck, lost their patients from pneumonia due to the introduction of food into the lungs. To avoid this danger, Thiersch has proposed the preliminary establishment of a gastric fistula.—*Le Progrès Médical*, Aug. 30, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 25, 1879.

THE INTERNATIONAL CONGRESS OF MEDICAL SCIENCE.

The sixth meeting of this congress took place at Amsterdam during the week from September 7th to September 13th.

The proceedings of a body with so pretentious a title are naturally to be judged from a high standpoint; and this year, in addition, they have to meet comparison with the exceptionally good work of the British and the French associations. The addresses delivered and papers presented, however, so far as they have yet been published, seem to have been worthy of the occasion, and to have furnished much new and valuable material to the profession at large.

The work was done in general sessions and in nine sections. Medicine and surgery, however, received the most notable contributions, while at the general meeting the addresses of President Donders and Professor Virchow excited the greatest attention.

The opening session was attended by nearly a thousand persons, mostly physicians, and these listened, it is said, with rapt attention to President Donders, who spoke for two hours upon the present condition of medical science and the importance of experimental physiology to its future growth. His address was delivered in French, the language adopted by the Congress as the common medium of communication.

Among the contributors of papers on the following days Englishmen and Americans were conspicuously absent. The meeting of the British Association a few weeks before had evidently drained the former dry, and America is too far away to be excited to much interest in a congress at Amsterdam. The meeting of the French Association for the Advancement of Science during the previous week had also diminished the number from that country. The majority of papers, therefore, came from Germany,

Austria, and Italy. The only prominent Englishman was Mr. Lister, who made what would seem to have been a very impassioned address in defence of his antiseptic method, and whose presence and remarks were received with much enthusiasm. Of Americans, Dr. Sayre made a very successful demonstration of the value of plaster-of-Paris jackets in Pott's disease, and Dr. E. Seguin discussed the metric system, as he had done previously at Cork and Montpellier.

The most interesting papers before the special sections were on medical subjects, and they were quite remarkable for their very practical character. The subject of phthisis was presented by four delegates. Dr. Stokvis related experiments showing that phosphoric acid and phosphates are not increased in the urine during any stage of the disease, but continue in about the same proportion as in health. While not denying the value of the phosphates in treatment, he considered it proved that they do not act by supplying an element drained from the system by the disease. A paper that excited more discussion was read by Mr. Delaunay, who asserted that phthisis was essentially a disease of warm climates; that in the north it was slow in progress and more amenable to treatment, while directly in proportion to its nearness to the equator did it become more rapid and fatal. He urged that, instead of having sanatoria in the south for northern invalids, there should be sanatoria in the north alone and for all.

In connection with the subject of fevers, a very interesting discovery by M. D'Arsonval, a distinguished young French physiologist, was announced. It consisted of an apparatus by which the amount of caloric thrown off in a given time could be accurately and easily measured. Previous methods have been very imperfect, but it will now be possible to measure the amount of heat generated under the various conditions of starvation, fever, putrid infection, and so forth.

In the more practical direction of the treatment of continued fevers, there were several contributions. Statistics in favor of cooling baths were given by Dr. Brondgest, who urged their special value with infants, and at the beginning of pyrexial conditions. Another writer advocated the douche in place of the bath, and from the descriptions it would appear that the idea of the Kibbe bed has been seized upon in the East. The author of the paper is Dr. Marcowitz.

The subject of metallotherapy was brought up in two papers, which are by far the most satisfactory contributions to this question that have been made for some time. Professor Eulenberg, of Greifswald, in a paper entitled "Researches on the Transfer of Sensibility," showed that such transfer is a physiological fact which is simply exaggerated in pathological cases. Thus, it was found that whenever a portion of the skin is made hyperæsthetic upon one side of the body, delicate tests show a diminution in sensibility

at a corresponding point on the opposite side; or, if one side be made anæsthetic, the other will be slightly hyperæsthetic. The demonstration of this fact, if supported by other authorities, will take from the theory of "expectant attention" a burden which it has been apparent was altogether too great for it.

As a complement to this physiological fact, MM. Proust and Ballet related certain experiments with magnets and metals upon persons suffering from organic hemianæsthesia. Even upon these they assert that a certain amount of transference of sensibility could be obtained.

The pathology of Bright's disease was discussed very exhaustively by Dr. Rosenstein. This gentleman announced what he seemed to consider a new classification of the various forms of this disease. Though possibly novel to the International Congress, it is remarkably like that taught in one of the colleges of this city, and need not be enlarged upon here.

Some very strikingly novel theories of this disease, however, were presented by Professor Semmola, of Naples. This learned professor states that the real chronic Bright's disease is a general affection—a defect in nutrition—in which the changes that take place in the kidneys do not constitute the primary cause of the principal symptoms of the disease. The gradual effect of moist cold upon the skin is the only true cause of Bright's disease. It acts by paralyzing the respiratory function of that organ. In consequence of this paralysis there are changes in the blood; the albuminoids are not perfectly assimilated or oxidized; there is an excess of albumen and deficiency of urea both in the blood and urine; these conditions in time producing the histological changes in the kidneys.

A bare statement of the theory by no means does it justice, and the author appears to have demonstrated some important physiological facts, whatever be the value of his generalizations.

In the section of surgery, aside from Lister's defense of his antiseptic method, perhaps the most notable event was the address by Professor Verneuil on the "Indications for Operation in Individuals suffering from Constitutional Diseases." While asserting the occasional necessity for operation in persons affected with constitutional diseases, such as cancer or scrofula, he argued that heretofore the results of such interference have not done much credit to surgery, and that if surgeons knew more of the diatheses with which they tampered they would not operate so often.

Prof. Van Gondever, in a paper upon lithotomy, spoke very disparagingly of lithotrity, and urged the especial value of the suprapubic operation; this he claimed to be best adapted for children in all cases, and to be often the best method for adults.

There were several contributions to orthopedic surgery—none, however, exciting the interest which Dr. Sayre caused by his demonstrations.

Gynecology received very considerable attention, as did also the departments of otology and ophthalmology.

Professor Virchow made an address upon medical education, in which he discussed especially the kind of preliminary training which the medical student should have had. He sketched out a preliminary course in the classics and the physical and natural sciences, which would be likely to quite paralyze the average American plough-boy ambitious to deal in pills. The address was delivered, contrary to rule, in German, and consequently did not receive the attention that its value deserved.

We have been able to give but a very slight sketch of the important work performed by this Congress. All that was done, however, is upon record, and whatever is of permanent value will reach, in time, the whole profession. It is as diffusers to the many of the knowledge gained by the more favored or competent few that such conventions deserve our utmost praise and encouragement, and none, perhaps, more than the International Congress, for, if properly conducted, there could be no agency so effective in making popular all that is new and good in medical science.

STATE SOCIETY'S TRANSACTIONS.

WE are in receipt of a number of pamphlets containing the transactions of certain State societies. We find ourselves very frequently favored with these productions, as there seems to be at present no organization which is content with anything less than an elegant edition of its annual proceedings.

The works before us give evidence of the value of State societies in stimulating, to a certain extent, scientific and practical inquiry, as well as in raising the general standard of the profession. They contain the usual assortment of articles. There are some very long papers, the offsprings of great occasions or discursive minds; there are presidential addresses adorned as ever with chaste rhetoric and poetical quotations; there are a good many papers written carelessly; and we find a few from the men of hobbies and unbalanced enthusiasms. There are, as is usual also, a good many papers that deserve wide perusal and attention.

It is a fact, however, that the proceedings of State societies do not, as a rule, represent in any degree the results of the observation and study of its members.

We may instance the State Society of Minnesota. This is a well-organized and practical body. It has adopted the custom of appointing committees on various subjects, and these committees issue circulars to the physicians of the State, requesting information upon these topics. The replies are collected and presented in a report. Theoretically this is very well; practically the replies are comparatively few, are often hastily written, and, individually, are valueless.

Collected, properly used, and extensively circulated, even a small number might be made of some value; but, issued as they are in a volume of transactions, they are essentially dead.

We repeat that State societies do not accomplish the high work that should be expected of them. We believe the reason lies to a considerable extent in the fact that the matter presented at its meetings is too often liable to perish with the session at which it is read.

The medical public does not get it: and few men will do hard work without the stimulus of a possible future appreciation of their efforts. A physician who has some good cases to work up or facts to collate, can hardly feel rewarded for weeks of labor by permission to tell his story before a small audience of professional brethren, or even by seeing it printed in a beggarly edition of society proceedings. We believe it should be the aim of societies to see that their best work is put in medical journals, and to make it understood also that a wide publication through such channels will be the reward of all conscientious work. The policy that has been adopted, or virtually so, by some societies, of trying to increase the value and sale of their transactions by excluding their papers from the journals, is simply suicidal. Transactions never reach the circulation of any reputable journal, and they are an inadequate medium for the diffusion of medical knowledge. We doubt if any one ever picked up a volume of transactions without having to blow the dust off first; if any one has, it is extremely creditable to the housekeeper.

There are, of course, certain records to be kept, and certain kinds of contributions which make these volumes a necessity; but it should be made clear among the working men of societies that the chief end of their labors is not the production of an annual volume, but a general diffusion of their work, through periodicals; while with such a stimulus there will probably be no remarkable epoch in medicine created, there will certainly be more creditable results from the annual meetings of medical men.

We shall not deny a certain lack of perfect disinterestedness in our thus urging societies to put their work, when possible, into journals. But, however this may be, it does not lessen the force or wisdom of the policy we recommend.

INTERNATIONAL QUARANTINE.—At a conference for the reform and codification of the law of nations, assembled Aug. 19th in Guildhall, England, Sir Sherston Baker read a paper on "International Rules of Quarantine." In it he propounded a scheme drafted in the form of forty articles, setting forth that an international bill of health might be granted by the local authorities to every vessel leaving its port, to be delivered to the authorities at its port of destination. The matter was referred to a committee for examination.

Reviews and Notices of Books.

THE NATIONAL DISPENSATORY, containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to the French Codex. By ALFRED STILLÉ, M.D., LL.D., and JOHN M. MAISCH, Phar. D. Second edition. Philadelphia: H. C. Lea. 1879.

We are pleased to see that a second edition of this great work has been called for by the profession. As it is but a few months since we reviewed it at length, it is now necessary to add that the volume has been thoroughly revised and somewhat augmented.

EYEBALL-TENSION—ITS EFFECTS ON THE SIGHT AND ITS TREATMENT. By W. SPENCER WATSON, F.R.C.S. Eng., B. M. Lond., Senior Surgeon to the Royal South London Ophthalmic Hospital, Consulting Ophthalmic Surgeon to the South London Medical Aid Institute, etc.; formerly Assistant-Surgeon to King's College Hospital. With woodcuts and illustrative cases. London: H. K. Lewis, 136 Gower Street. 1879. Pp. 70.

In his preface the author says he has "adopted the term *eyeball-tension* in preference to *glaucoma*, as being more expressive of the acknowledged condition of the eye in the disease in question," etc. We think the profession will object to this change in nomenclature as being not very well founded. All eyeballs, whether diseased or not, have eyeball-tension. Some have increased tension, some diminished tension, and some normal tension. If we wish, then, to substitute for *glaucoma* the name of the most constant symptom of that disease, we must say "increased eyeball tension." This name would not only be inconveniently long, but in those cases of *glaucoma* which now and then turn up, in which the tension is normal, or even diminished, would be a misnomer.

It is also well known that the tension of the eyeball may be increased in other diseases than *glaucoma*. All things considered, probably we cannot do better than to adhere to the well-understood and generally accepted name, *glaucoma*.

We cannot help wishing that the author had tested the vision in his cases by the modern method—that of Snellen—instead of telling us that the patient could read "J.2." or "J.10." without giving us the distance at which he could read it. We are thus left without data from which to estimate the exact amount of vision in each case.

We are also sorry to find no information in regard to the *refraction* of his cases, either in those tabulated or in those detailed in the appendix. But notwithstanding these and a few other defects, the book is a readable and instructive one. Nowhere have we seen a more simple and natural classification of the different forms of *glaucoma*, or a more lucid explanation of the various theories in regard to its causation than in Chapter I.

In Chapter II. the author gives a succinct history of the rational treatment of *glaucoma*, describes and comments upon the several operations performed for its relief, and gives us his impressions as to the value of *eserine* and *pilocarpine* in the treatment of *glaucoma*.

On page 14 he says: "*Eserine* is very valuable in chronic cases." This statement does not agree with the general experience of ophthalmologists.

Contrary to the author's experience (page 18) we have seen several cases in which acute *glaucoma* at-

tacked the fellow-eye within a day or two after iridectomy for *chronic* glaucoma. We have also seen more than one case in which "iridectomy performed on one eye hastened the access of the disease" in its fellow, the latter having previously shown no premonitory symptom.

We would recommend the book to the profession as the best monograph on the subject in the English language.

ON DISEASES OF THE STOMACH; the various Forms of Dyspepsia: their Diagnosis and Treatment. By S. O. HABERSHON, M.D., London. Third edition. Philadelphia: Lindsay & Blakiston. 1879. Pp. 324.

A book that has already gone through two editions seldom calls but for a short notice from the reviewer, and this volume of Dr. Habershon's is no exception to the rule. It is written in a pleasing style, and treats of diseases of the stomach in a practical manner. It is divided into twenty chapters, fifteen of which are devoted to a consideration of the different forms of dyspepsia, while the remaining treat of Degeneration, Ulceration, Cancerous Disease, and Spasm of the Stomach. Our author, in the management of diseases of this viscus, rightly places medicines secondary to proper diet, and protests against the too common custom of constantly dosing dyspeptics with drugs which, in the end, leave the patient in a worse condition than at the beginning of treatment. We can cordially recommend this book of Dr. Habershon's to the profession.

A GUIDE TO SURGICAL DIAGNOSIS. By CHRISTOPHER HEATH, F.R.C.S., Holmes Professor of Clinical Surgery in University College, London, and Surgeon to University College Hospital; Honorary Fellow of King's College, London. Philadelphia: Lindsay & Blakiston. 1879. Pp. 214.

MR. HEATH is so well known both as a practical surgeon, teacher, and writer, that anything from his pen requires no introduction from the hands of a reviewer, and scarcely any notice but the announcement of the fact that he has written a book. He says in his preface that "having been a clinical teacher for some years, I have constantly been struck with the difficulty which even a well-read student finds in bringing his knowledge to bear promptly and efficiently upon the patient before him. The recognition of the several symptoms which the student has learned in lectures or by reading can be best directed by the teacher at the bedside; but in his absence it is not always easy for the student to get a clue to the nature of the case before him. An attempt is made in the following pages to afford this assistance. . . ."

The first chapter is on case-taking, in which he gives a general plan of the proper manner of recording the history of a patient, the course and treatment, which many practitioners who report their cases for medical journals would do well to study with care; they could certainly do so with profit. The arrangement of the subject-matter is not in two columns, but the surgical diseases are considered in paragraphs, with marginal notes of the subject of each section. There are throughout the book tables of differential diagnosis; thus of "concussion and compression of the brain," of "ulcers of the face, injuries about the shoulder," etc. The character of the work can be better illustrated by a quotation taken at random—thus, on page 202, § 453:

"*Osteomyelitis*—A swollen, tense condition of a stump in which there is no 'pocketing' of matter, accompanied by a great rise of temperature, and a rapid, feeble pulse, is apt to be followed by profuse

discharge of effusive pus from the medullary canal and around the bone, which will be bare, the case being one of *osteomyelitis*, or inflammation of the medullary membrane. Symptoms of pyemia may at any moment arise in such a case."

OPHTHALMIC OUT-PATIENT PRACTICE. By CHARLES HIGGINS, F.R.C.S., Ophthalmic Assistant Surgeon, Guy's Hospital; Lecturer on Ophthalmology, Guy's Hospital Medical School. Second Edition. Philadelphia: Lindsay & Blakiston. 1879.

This little book of 116 pages seems to be a *résumé* of the author's lectures on Ophthalmology at Guy's Hospital. Being devoted exclusively, as its title indicates, to out-patient practice, only the most common affections of the eye, and such as come most frequently under the observation of the general practitioner, are touched upon.

The author has a happy faculty of stating concisely and clearly the more important points in the diagnosis and treatment of each disease spoken of, and as far as it goes, the work seems to be, for the most part, fully up to the times.

Some of the statements are, however, open to criticism. For instance, on page 31, it is stated that "the presence of nodules of lymph upon the iris shows that the iritis is syphilitic." Most ophthalmologists must have seen exceptions to this rule, and it is now very generally understood that there is no one unfailing diagnostic symptom of syphilitic iritis.

In purulent ophthalmia the author recommends (page 19) that a "bag of ice be laid upon the closed lids during the intervals at which the lotion is applied." We have found the weight of a bag of ice a serious objection, and that iced cloths, consisting of two thicknesses of old muslin or linen, frequently changed, are much more agreeable to the patient. The author fails to mention that, in these cases, operative interference, as canthotomy or paracentesis, is frequently necessary to save the eye.

The method of slitting up the canaliculus described upon page 47, is a somewhat antiquated one, and is now resorted to only in exceptional cases. The operation is almost universally performed with a probe-pointed knife, and without the use of a grooved director. Neither is it now the usual practice to wait five or six weeks after slitting up the canaliculus before trying "to relieve the structure (stricture?) of the duct by passing probes."

On page 101 it is stated that the retinal "veins are distinguished from the arteries . . . by the fact that the arteries are marked by a double contour, their margins being considerably darker than their centres." A little careful observation will convince any ophthalmoscopist that there is a light streak along the centres of the retinal veins as well as arteries.

The book is, in the main, a good one, however, and may be read with pleasure and with profit by the general practitioner, for whom it is evidently intended.

A NEW FUNCTION FOR THE SYMPATHETIC SYSTEM.—Dr. R. M. Bucke, Superintendent of the Asylum for the Insane at London, Ont., in an elaborate essay upon the moral nature of man, asserts that its seat is not in the cerebrum, but the sympathetic system. Some such idea was formerly advocated by Bichat, who contended that the passions were located in the organs of organic life. The close relation between emotional changes and functional derangements of the various viscera led to this idea.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, September 24, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

SUBPERIOSTEAL EXCISION OF ELBOW.

DR. LANCE exhibited a patient upon whom he had performed subperiosteal excision of the right elbow-joint, after Prof. Voight's method, and gave the following history: Patient was nineteen years of age, and had a stiff right elbow from his early childhood. He knew nothing about the cause of this trouble. The arm remained thin and powerless, and any exercising caused pain in the joint, especially during the last two years. Various methods of treatment were employed but without avail, and the patient finally resolved to get rid of his trouble by an operation.

At that time the patient was in good health. The right elbow was ankylosed at an angle of 90°, with a mobility of nearly 10°. The tissues about the joint were somewhat thickened, but no fistula or other indication of existing suppuration was present. The olecranon and head of the radius seemed thickened, and they were very painful on pressure, showing chronic osteitis. The operation was performed on the 25th of June by means of a bilateral incision, antiseptically made without spray, and by the bloodless method. The periosteum was carefully preserved; in all those places where important tendons or ligaments had their insertion (olecranon, coronoid process, epicondyles of humerus, etc.), thin layers of bone were separated by means of hammer and chisel, and remained in connection with the periosteum, according to the plan of Voight.

The operation was somewhat tedious and difficult, the periosteum being thickened and tense, and all recesses of the joint obliterated. Lister's gauze dressing was applied. The after-treatment consisted of a dorsal splint of plaster-of-Paris, with elevated position and slight extension. The position of the arm was about 150°. After the tenth day position was changed every second day to the extent of from 75° to 150°. At the end of third week, articulated silicate dressings (with shoulder-piece), which had a movable joint and rubber strips, were applied corresponding to the new joint. The joint allowed a slipping of the bones of the forearm upward and backward, according to the physiological position of the ulna. Active and passive movement were freely practised by causing the patient to lift a box filled with sand, the amount of which was increased every day. These exercises effected a stretching of the elbow. The arm, by means of the strip, was held in a right angle. The weight of the sand was chosen always a little beyond the strength of the patient to master it, so that it slowly extended the arm, the patient endeavoring to prevent this, and struggling against the weight by the power of his muscles. The rubber strips kept up a passive dragging of the ligaments and held the bones in a certain adaptation.

After the seventh week the apparatus could be omitted, the new formation of the bones being very significant, and almost complete cicatrization had been complete at end of fifth week. There had not been any significant discharge since the second week, only those places discharging superficially where the drainage-tube had been introduced.

The reaction after the excision had been quite in-

significant. A bloody infiltration of the arm and forearm disappeared under the physiological changes of color, and was reabsorbed without interfering with the healing process.

When the patient was exhibited to the Society, just three months after the operation, the elbow presented nearly its normal shape. Motion was between 80 and almost 180 degrees, without any abnormal lateral mobility. The condyles of humerus appeared stronger than normal. Pro- and supination almost normal (had been exercised also methodically every day, the apparatus being removed for this purpose). The head of the radius was well marked, and normally faced the external condyle. The olecranon was distinctly formed, but was a little smaller than normal. Above its apex something like a sesamoid bone could be felt in the triceps tendon. The arm was so strong that the patient was able to lift a chair, seizing it by the leg, and after stretching the arm he held the chair a good while in the air. The flexion to an acute angle was difficult. The specimen showed deep depressions in the articular part of the ulna, especially one behind the base of the coronoid process. Its walls were hard and smooth; they were covered by a dense fibrous tissue which surrounded a small quantity of cheesy matter. All the depressions in the bone were filled with a succulent fibrous tissue, which sent vascularized adhesions to the opposite cartilage; so the process was on its way to cicatrization. The bones of the humerus were almost normal; cartilage of radius showed some cicatricial depressions; its head had an abnormal process toward the articulation, with the ulna, which was entirely obliterated by a dense fibrous mass.

ERECT LUXATION OF THE HUMERUS.

A vigorous laborer, about forty-five years of age, when rolling a heavy piece of ice along an inclined plane, lost his balance, and, in tumbling forward, seized, by the elevated right hand, the projecting border of a barrel of beer, a series of them forming a comparatively narrow path. He fell down in spite of that, and felt "that something was turned out in his shoulder when he was in the air." He could not get up alone, and the arm remained in the erect position. Dr. L. saw him eight hours after injury, in consultation with Dr. Assenheimer. The patient was in bed, with the arm elevated to about 120 degrees, stretched in the elbow, hand in supination. He held with his hand a string, which had been attached to the upper border of his bedstead. Every sinking down of the arm caused a severe pain about the upper end of the middle third of the humerus, perhaps in consequence of dragging of the coraco-brachialis muscle; deltoid relaxed. There was a deep depression below the acromion. The head of the humerus could clearly be seen below the coracoid process and exceeding its line toward the middle line so that about the tubercle corresponded to the end of the coracoid process. The axis of the humerus corresponded to a line which might have crossed the articulation of sternum and third rib. If the patient made a strong lateral curvature of the trunk, so that the short ribs almost touched the crest of the ileum, and if at the same time he lowered his scapula as much as possible, he, when sitting, was able to rest the wrist upon the knee. The arm was prevented from falling by the coracoid process, and perhaps the pectoralis minor. The reduction was made without chloroform, patient sitting on a chair. The scapula was fixed by means of a towel. The elevation was increased, and after extending as much as possible, the arm was lowered, when the head of hu-

merus slipped forward under the coracoid process, and was placed against the border of the glenoid cavity. A further slight rotation inward made it slip to its normal position without difficulty. Recovery took place in a comparatively short time, so that after three weeks he was able to resume his work.

LARGE MAMMARY TUMOR.

Dr. A. C. Post exhibited the segment of an enormous tumor of the mammary gland, which he had removed by operation from a lady over sixty years of age. The whole tumor, after its removal, weighed nineteen pounds. It had existed for about fifteen years, was small when first observed, and grew very slowly. During the past three years it had grown rapidly, and finally reached such a size as to occasion extreme inconvenience and to prey upon her health. Dr. Post saw her early last spring and advised the removal of the growth, at the same time telling the patient that the operation was a hazardous one. She did not make up her mind to follow the advice until last July, when a hemorrhage occurred from an ulceration on the surface of the growth.

The operation was performed with the assistance of Dr. Sands, of this city, and Drs. Barker and Owen, of Morristown, N. J. The subcutaneous vessels were enormously enlarged, and it required very careful dissection to separate the integument from the tumor. The patient became very much exhausted while on the table, requiring repeated hypodermic injections of brandy. After the operation she had a very feeble pulse, and died in the course of an hour. The tumor was fibro-cystic in character.

YELLOW FEVER—FATTY LIVER—PARENCHYMATOUS CHANGE IN THE KIDNEYS—URÆMIC COMA.

Dr. SATTERTHWAITE presented the liver, spleen, and kidneys, and microscopic sections from a patient who died in the Presbyterian Hospital, of yellow fever, on July 29th.

The following was the outline of the clinical history prepared by Dr. Wetmore, of the hospital staff, and Dr. W. H. Porter had prepared the microscopic sections:

Margaret Cregan, *æt.* 32, Ireland; widow; stewardess; was admitted July 25, 1879. Family history excellent. Personal health had always been good. Her illness dated back only five days, *i. e.*, it commenced July 20, 1879. She then had frontal headache and general "soreness all over her back and legs." At 10 A. M., on the 20th, she had a severe chill, followed by some fever. There was nausea, but no vomiting; there was also some diarrhoea. She had chills night and day, with fever and sweating, for the five days preceding admission. When admitted her temperature was 105° F., pulse 108. The diagnosis of remittent fever was made, and she was given cinchonidia sulph., *gr. xx.*, in divided doses. The symptoms at that time were manifestly insufficient to establish the subsequent diagnosis.

On the following day the pulse had fallen to 98; temperature 104° F.; and in the evening to 92; temperature 101½° F. The patient slept most of the day. She had some diarrhoea, but no pain. Her diet was milk chiefly. The urine examination gave the following results: *sp. gr.* 1020; color, amber; reaction, alkaline; odor, ammoniacal; sediment, yellowish-white; albumen, half volume. The amount of urine could not be ascertained, because it was passed with the evacuations from the bowels. Microscopic examination revealed triple phosphate and urate of ammonia crystals, with some granular casts and blood-corpuscles.

On the seventh day (July 27th) the pulse had again

fallen in the morning from the figures of the preceding morning; it was 94; temperature 102½°. In the evening the pulse was 90, and temperature lower again (101).

On July 28th, the eighth day, she vomited occasionally, though the cinchonidia was kept down half an hour. Pulse 88, and temperature the same as the preceding night, *i. e.*, 101; evening, pulse 80, temperature 101. The vomited matter was white (probably the milk she drank). The diarrhoea continued. The color of the passages was light yellow. Menstruation occurred this afternoon.

July 29th (ninth day).—The night was passed with comparative comfort. Twice she vomited some dark matter. Jaundice was now noticed for the first time. The pulse was now weak and she was delirious, recognizing no one. The second sound of the heart was almost imperceptible. Respiration labored, and 30 per minute. At noon it was found that she had passed no water since 6 A. M. Hot cloths were then applied to the bowels, and she was cupped over the kidneys; no œdema anywhere. Shortly afterward a catheter was introduced, and brought away a drachm of dark urine. It contained 50 per cent. per volume of albumen. The microscope also detected blood and the epithelium that is described as renal. Pulse was 88, and temperature 99½°.

As it was plain she was suffering from suppression of urine, cups were again applied over the kidneys, and one-quarter of a grain pilocarpia hydrochlor. was injected hypodermically. She died at 1.50 P. M. Autopsical examination twenty-one hours after death, by Dr. W. H. Porter, curator to the hospital, in the presence of Drs. E. C. Janeway, W. De F. Day, and E. B. Ramsdell:

External examination.—Rigor mortis well marked; body well provided with fat, and in a good state of preservation; general jaundice of the skin; numerous ante-mortem ecchymoses on the lower extremities, together with the usual post-mortem discolorations on the under surface of the body and limbs.

Dr. PUTNAM-JACOBI asked if there were any evidences of the reabsorption of bile. This seemed a possible condition, in view of the fact that the liver-cells were atrophied.

Dr. SATTERTHWAITE remarked that the liver-cells were filled with oil-globules and granular fat, and were rather swollen than otherwise.

Dr. PUTNAM-JACOBI thought that a distinction should be made between fatty degeneration in which mere globules were deposited and that condition in which only granules were present.

Dr. SATTERTHWAITE did not think that there was, practically speaking, any difference between these conditions.

Dr. PUTNAM-JACOBI was of the opinion that a distinction should be made between fatty infiltration and fatty degeneration of liver-cells. In the former cases the cells became broken down, and in the latter their functions were not markedly impaired.

Dr. SATTERTHWAITE thought that the particular size of the oil-globules was not of so much account as their relative position in the substance of the hepatic lobule. If the deposit had extended to the centre of the acinus around the hepatic vein, the function of the liver was interfered with, if not entirely abolished. On the other hand, when the so-called simple fatty degeneration took place, there was usually a deposit of oil merely in the cells at the periphery of the lobule.

FOREIGN BODY IN THE EYE.

Dr. KNAPP exhibited an eye removed by operation

from a man sixty years of age. The organ had contained a foreign body for two years. The patient, at the time of the accident, was passing by a man who was pecking a mill-stone, when he felt that some sharp body entered his eye. Dr. Knapp saw him at the end of eight months afterwards, and discovered a shrunken and movable cataract in the injured eye. As no foreign body was discovered, Dr. Knapp thought that it was enveloped in the cataract. Last June the patient presented himself again, with well-marked irritation in the eye. Extirpation was advised accordingly. On examining the eye afterward, the membranes, except the crystalline lens, were completely normal. At the bottom of the ciliary processes a small piece of iron was discovered, but there was no new formation of connective tissue. In the absence of the latter, Dr. Knapp did not think it impossible that the foreign body had been originally encapsuled in the cataract, and that by a shrinking of the cataract it had fallen to the position where found.

AN INTERESTING CASE OF EXOPHTHALMUS.

DR. SEGUIN presented a photograph of a patient with a remarkable exophthalmus. The patient came to the Manhattan Eye and Ear Department on account of projecting eyeballs. Dr. Webster found, in connection with that condition, a pulse ranging from 92 to 96, and the anterior portion of the neck normal. There were no other symptoms in the case. The point of interest centred in the fact that the exophthalmus was the only symptom of Graves's disease which was present. Again, the cause of the disease could not be explained by the mere contraction of Müller's muscle. The unusual point in this case was disease of the optic nerve. There were no evidences of a pulsating tumor.

DR. KNAPP referred, in this connection, to sixty cases of exophthalmus which were on record. Only in a very few of these was aneurism found. In quite a large number the carotid was tied, and some of these cases were cured. He had never met with a case of Graves's disease combined with disease of the optic nerve.

DR. SEGUIN asked if there was any bruit in these cases.

DR. KNAPP answered that such a bruit was subjective in the majority of cases.

OBLETION OF THE PANCREATIC DUCT.

DR. BEVERLEY ROBINSON presented a specimen of obliteration of the pancreatic duct due to carcinoma, and accompanied with great emaciation. The history of the case was given in detail:

George Davis, *et.* 27 years; English; groom; unmarried. Admitted to hospital June 28, 1879. About one and a half months ago he lost appetite, and about a month ago began to vomit everything he ate soon after taking food. Never saw any blood in vomits. This condition continued up to the present time. Had pain in the stomach after eating. Abdomen has been distended for about two weeks; legs and feet became swollen about the same time. Passes very little water; bowels regular. Has grown weak and thin. Urine normal. Fluid in peritoneal cavity. Liver cannot be made out. Apex-beat of heart in third intercostal space, above the nipple, and synchronous retraction in fourth interspace.

July 30th.—Paracentesis performed, and 344 ounces of pale yellow fluid, somewhat cloudy, was drawn off.

July 31st.—Urine normal. Liver not felt. A nodulated growth was felt in the median line, below the border of the ribs and extending to the right.

August 8th.—Scanty urine for several days. Today passed $\bar{5}$ ix.

September 18th.—Patient has vomited almost daily since admission. No blood has been seen in the vomit. Died of asthenia.

September 19th.—Post-mortem examination. Rigor mortis well marked. Cadaver much emaciated. Abdominal cavity filled with clear straw-colored fluid, distending the abdominal walls, and pressing up the diaphragm. Lungs and heart very small. Kidneys normal. Intestines atrophied and walls thickened; surface of rectum covered in spots with fibrinous nodules. Mesentery also covered with fibrin. A small piece of omentum only remained floating about loose in the abdominal cavity. Stomach, intestines, pancreas, and liver were firmly adherent. At pyloric end of stomach, on posterior surface, was a tumor involving the pyloric orifice, which was about the size of a goose-quill. The pancreas was almost completely obliterated by the tumor. Liver small. Gall-bladder small, and cystic-duct obliterated; hepatic duct and common bile-duct free.

The question having arisen as to the significance of fat in the stools in diseases of the pancreas, DR. PUTNAM-JACOBI remarked that while fatty stools were not always present in such cases, they did sometimes exist when there was simple ulceration of the duodenum.

DR. SATTERTHWAITTE stated that primary cancer of the pancreas was almost unknown. It was almost without exception a secondary disease to cancer of the stomach.

DR. JOHN C. PETERS, in this connection, referred to a case of cancer of the head of the pancreas which came under his observation some months since, in which pressure upon the pylorus caused enormous distention of the stomach. The history and specimen had been presented to the Society.

RAPID LITHOTRITY.

DR. KEYES exhibited calculi removed by rapid lithotripsy from a physician aged seventy-three. He had suffered from the symptoms of stone for a number of years. The calculi, which weighed altogether ten and a half drachms, were removed in an hour and twenty-five minutes. This long time was due to the difficulty in grasping the largest stone, which was an inch and a half in diameter, and situated in a sacculated portion of the bladder posteriorly.

Dr. Keyes also took occasion to exhibit Sir Henry Thompson's new instrument, which had been used on that occasion.

Dr. Keyes also exhibited small renal calculi which had evidently passed through the ureter into the bladder without producing pain.

DR. PETERS referred to a similar case in his practice.

Correspondence.

CAUSES OF SUDDEN DEATH DURING THORACENTESIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Dr. Putnam-Jacobi, in the response written to our criticism of her letter on "Causes of sudden Death during Thoracentesis," agrees with us in believing that the cause in question is "exaggerated cardiac diastole," as she calls it. We evidently did not quite understand Dr. Putnam-Jacobi's position in regard to the question from her first communication. We must still beg leave to differ, however, in respect to the causes of this "exaggerated diastole."

In speaking of our theory that the cause of the "exaggerated diastole is the influx of venous blood,"

Dr. Putnam-Jacobi says, "it is evident that this" (*i. e.*, influx of venous blood) "is consequent upon the exaggerated diastole of the heart," *i. e.*, what we consider to be a cause is "evidently" to the doctor an effect. To us this is not evident.

The direct effect of the aspiratory force in causing cardiac dilatation (*i. e.*, leaving out of consideration the dilatation which we believe to be produced by the forcing in of blood from the veins) is due simply and solely to the dilatation of those contents of the heart which are capable of expanding when atmospheric pressure is lessened. The only substances which can do this are the gases. The dilatation of the heart, therefore, which results directly from the aspiratory force exerted on it can be produced only by the expansion of the gaseous contents of the heart. These gaseous contents consist of the oxygen, carbonic acid, and whatever other gases are contained in solution in the blood or tissues. If the heart was composed of perfect solids and perfect liquids only, the aspiratory force might exert itself for a century and not enlarge it one hair's-breadth. It must be firmly held in mind that there is really no force whatever outside of the heart tugging at it and forcing it to dilate. The dilating force, if the heart had no communication with the veins, would be simply and solely the expansive power of its contained gases, which, having been absorbed under an atmospheric pressure of about fifteen pounds to a square inch, are partially relieved from that pressure by the creation of a partial vacuum in the rigid-walled space in which the soft bag, the heart, which contains them, is suspended. It is this expansion which Dr. Putnam-Jacobi apparently believes to be the sole and sufficient cause of the fatal dilatation of the right ventricle. It is an expansion so caused, moreover, which induces the venous blood to rush to the ventricle from the veins. The atmospheric pressure in the right heart is below normal. The atmospheric pressure on the veins is normal. Yet Dr. Putnam-Jacobi believes that the influx of blood from the veins to the right heart "is consequent upon the exaggerated diastole of the heart."

It seems to us that Dr. Putnam-Jacobi has fallen a victim to the false conception involved in the term "negative pressure" to which we called attention in the RECORD of September 27th, *i. e.*, Dr. Putnam-Jacobi has supposed that the fatal dilatation of the heart was the cause of the venous influx, whereas it seems perfectly evident, on thorough analysis of all the forces at work in the problem, that the venous influx is the cause of the fatal dilatation of the heart.

After the above analysis it is perfectly obvious that as soon as atmospheric equilibrium is restored, these expanded gases will at once be reabsorbed, and the right heart abnormally distended by this abnormally large bolus of blood (which has been forced into it simply and solely by the atmospheric pressure from without pressing on the veins and squeezing the blood into the heart till equilibrium is restored), fails to respond to the increased strain. The expansion of the right heart caused by expansion of gases before the blood is forced in, seems to us an unimportant factor in the problem (see below).

In this resulting paralysis there exists inability of the muscular fibre of the heart to contract under the increased strain, either from insufficiency of the intrinsic contractile power of the fibre, insufficiency of the stimulus to contraction (nerve-force), or both. Dr. Putnam-Jacobi claims that it is insufficiency of nerve-force, which results from assumed preceding lessened activity of the heart, which causes the failure of the cardiac contraction under the strain. It seems to us

that it can be conclusively demonstrated (see below) that if this insufficiency exists, it must be the result of over-, not of under-work, to which cause of weakness we should add malnutrition. Dr. Putnam-Jacobi has not alluded to the possible effect of the excessive dilatation directly on the muscular fibre itself. How to demonstrate which, if either factor predominates, we don't know. It seems to us, however, that over-distention of muscle may have quite as much to do with the question as insufficiency of nerve-force. This, however, is pure conjecture.

With reference to the movements of the chest-wall after aspiration, we must again emphasize the fact that after paracentesis, under the circumstances which we are now considering, the "long-immobilized chest-wall don't and can't expand at all."

The reasons why it is immobile during pleurisy is, first, that the half-thorax is so distended by the effusion that it is an anatomical impossibility for it to expand any more; or, second, because pleuritic adhesions or thickening of the pleura exist, which resist the efforts of the muscles of inspiration. The immobility resulting from effort to suppress pain is, of course, out of the question in such cases as we are referring to. If we draw off this fluid and make a partial vacuum in the affected side of the thorax, the affected side, to expand, must obviously exert an expansive force strong enough to overcome the resisting atmospheric pressure. This, in all probability, it cannot do.

Dr. Putnam-Jacobi believes that the cause of sudden death under the circumstances in question is "exaggerated diastole of the heart," caused by this so-called "negative pressure." The writer has tried the following experiment: He has closed his glottis at the end of deep expiration, and then inspired with all his strength. Although he is an adult male of fair muscular development and in good health, he was not able to inflate his chest to any very appreciable extent. Moreover, the "negative pressure" applied to the heart was not great enough to paralyze the right side of his heart, or even to cause faintness. What reason have we then to suppose that the feeble inspiratory muscles of an exhausted patient could expand the chest-wall against a pressure so great as to cause not only faintness but instant death? There can be no "outward movement of the thorax" to direct "aspiratory force" with "abnormal intensity upon the heart." The thorax is being clamped and crushed in while the blood is being crammed into the right heart. This throws the question of the influence of thoracic expansion entirely out of the problem. The pressure of the atmosphere on the outside of the thorax, which tends to press everything on which it impinges—solid, liquid, or gas—into the artificially produced vacuum, is the only force to be considered. Compared to this, the force of inspiration is inconsiderable. If this was not so, suicide might be conveniently committed by simply closing the glottis and making a forced inspiration; spasmodic croup would be invariably fatal, etc.

Dr. Putnam-Jacobi is right, in some cases at least, when she says that the "cardiac ganglia must have been obliged to expend less force than usual to antagonize them" (*i. e.*, the respiratory movements during chronic pleurisy. We laid too much stress on compensatory expansion of the unaffected side. We, moreover, agree perfectly with the assumption that "simple collapse of the lung, more or less deprived of air, does not offer a formidable obstruction (*i. e.*, to the circulation through the lung) any more than do unexpanded fatal lungs (italics ours). Unfortunately for Dr. Putnam-Jacobi's theory, a stronger demon-

stration of the falsity of that theory than this same analogy could not have been chosen.

One peculiarity of the foetal circulation is that the most of the blood which enters the right ventricle is forced into the aorta through the ductus arteriosus. Its labors, moreover, are reduced by the passage of blood through the intra-auricular foramen, from the right into the left auricle. At the moment of birth, when the lungs expand, the mass of blood from the right heart ceases to pass through the ductus arteriosus and foramen ovalis, and enters the lungs. This physiological process proves beyond a doubt that collapse of the lungs *does* cause obstruction to pulmonary circulation, and therefore *does* increase the labor of the right side of the heart in pleurisy with effusion—unless, indeed, the individual affected happens to be a foetus, or unless Nature, with unusual foresight, has not only left him a ductus arteriosus and a fenestra ovalis intact, but has also caused them to grow with the growth of his blood-vessels!

This obstruction must, it seems to us, infinitely outweigh the trifling ease which the heart may have from possible diminution of aspiratory force. We must then adhere to our original belief, that sudden death occurring during thoracentesis depends on over-distention of the right heart caused by atmospheric pressure, which forces the blood from the peripheral veins into the thoracic veins and right heart, to fill the partial vacuum produced by the operation.

Very truly yours,

R. VAN SANTVOORD, M.D.

66 WEST ELEVENTH ST., Oct., 1879.

“PITHING” AND THE VASCULAR SYSTEM.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In your issue of September 13th I endeavored to show that the doctrine taught in our text-books, as to the relations of the central nervous system to arterial contraction, is incorrect; that, after destruction of these centres, instead of being dilated, the arterial system is contracted and empty, as a result of which contraction the blood is transferred to the veins, which are proportionately distended. Dr. R. Van Santvoord comes to the rescue of the popular doctrine, in your issue of Oct. 4th; and in doing so, claims, among other things, that such alleged contraction of the chief arteries of the systemic system is impossible, on the ground that “contractile fibres are to be found in considerable numbers only in the smaller arteries,” and “not in the large vessels at all.”

It is well known that the smaller arteries are much more amply supplied with muscular contractile fibres than the aorta; and, as a consequence, that it is upon these that the influence of vaso-motor innervation is more actively displayed. We do not pretend that in general—and least of all, in the larger and older animals—the aorta would undergo a reduction in calibre sufficient of itself to empty the systemic arteries of blood; but if, in our former article, which was necessarily much condensed, we have not laid sufficient stress on the influence of the smaller arteries in emptying this system into the veins, we believe our general position is quite tenable, and that your correspondent goes too far in denying the presence of contractile fibres in the larger arteries. A reference to the authorities shows that even the aorta is fairly supplied with muscular fibres, and that “contraction of the arterial system,” including its chief vessels, is a phrase frequently employed by physiological writers.

In Gray's Anatomy it is stated that as many as forty layers of non-striated muscular fibres have been counted in the wall of the aorta, interspersed with layers of fine elastic tissue. Todd and Bowman describe the same, and even furnish an illustration of the muscular fibres in the aorta of a horse, with their nuclei. Dr. George Harley, in his “Histological Demonstrations,” points to the smooth muscular fibres in the wall of large arteries. Dr. Burdon-Sanderson, in the “Handbook,” gives directions how the muscular fibres of “the large arteries” may be demonstrated; and in the same work he states that the increase or diminution of arterial pressure is in great part, if not entirely, dependent on contraction of the arterial system (p. 251). This phrase—“the arterial system”—cannot here be held to exclude the aorta and its chief branches. Drs. Todd and Bowman write: “The existence of two forces in the arterial wall, one of simple elastic reaction, the other of a slow muscular contraction, is shown in the well-known experiments of John Hunter,” performed on the aorta of a horse (Path. Anat., p. 655). Dr. W. B. Carpenter states that “Valentine and others have succeeded in producing evident contractions of the aorta by irritation of the sympathetic nerve and of the roots of the cervical nerves of the spinal system.” (Human Phys., p. 483.) Prof. Kuss, writing of “the arterial system,” says the arteries “are not, as we should be likely to suppose, hollow cylinders, but rather hollow ribbons with flattened sides.” When full of blood, their form is that of a cylindrical tube; but “in cases of severe hemorrhage they assume their natural ribbon-like form; they assume it also after death, by *ejecting their contents into the capillaries and veins.*” When, in death, the arteries are opened and air admitted, he states, they lose their ribbon-like form and become cylindrical, “which form is due to the antagonism between the muscular and elastic tissue.” This reference to elastic tissue, and his remarks generally, show that it is to the aorta and large vessels he here refers; since, as Prof. Kuss states, with few exceptions only, it is at the summit of the arterial cone (aorta) this tissue is found in the vascular system. (Lectures, pp. 152-3.)

Dr. Burdon-Sanderson, in treating of the circulation in asphyxia, alludes to the deprivation of oxygen in the circulating blood in determining “general contraction of the smaller arteries;” and adds, “the immediate consequence of this contraction is to fill the venous system.” (Handbook, p. 333). Dr. Van Santvoord disputes the assertion that venous distention can result in this way; and gives it as his opinion that, “if the small arteries had contracted [as we asserted they did], the blood would have been dammed back in the great vessels and heart.” Here he is at variance with Prof. Kuss and Dr. Burdon-Sanderson; and, as we merely adopted their view of how the mass of the blood was transferred to the veins, he must settle his objection with them and not with us.

We think we have shown conclusively that the aorta and its chief branches are supplied with muscular contractile fibres; that they are capable of contraction, and if so, of assisting in the process of expelling the blood from the systemic vessels. But even if the “ejecting of their contents into the capillaries and veins” depended on the action of the smaller arteries alone, our arguments would suffer nothing. The point we have sought to make is the general one, that the accepted view of the relation of the vaso-motor centres and nerves to the vascular system is untenable. It is authoritatively taught that

vascular contraction (of the smaller arteries if you like) is the result of vaso-motor excitation. But here in a pithed animal, when the vaso-motor centres are not excited but destroyed—in ordinary death too, when nerve-force is extinct—the arterial system is contracted to the full extent of which it is capable. That is to say, arterial contraction takes place quite independently of nerve-force, or rather in its entire absence. Again, it is authoritatively taught that arterial dilatation is the result of vaso-motor paralysis,—that the muscular fibres of the arteries being no longer urged to contract by nerve influence, yield to the pressure of blood, and dilate. Why, then, are they not dilated in the death of the body, instead of being, as the authorities agree, contracted so as to eject their contents into the veins? And why has it been claimed that death by pithing furnishes an exceptional state of the arteries compared with death from other causes; that here the arteries are dilated, when as a matter of fact the contrary condition prevails? We can only account for these and other anomalies by the exigency of the present vaso-motor theory, and by an oversight in not testing it with the facts, with which we claim it is perpetually out of joint.

We referred in our former article to the effects of a glass or two of brandy in causing flushing, when, as a stimulant to the vaso-motor nerves, it ought (on the theory) to have produced vascular contraction and paleness. We cannot see that Dr. S. has met our point, and we think he misapprehended our meaning from not perceiving the full scope of our theory. We claim that nerves and muscles are antagonists: that while the vaso-motor nerves *dilate* the arteries, the contractile power of the muscular tissue of their walls is constantly exercised to reduce their calibre. A glass of brandy in a dose of nitrite of amyl, gives a stimulus to dilating nerve-power and arterial expansion with flushing results. A dose of aconite, veratrum viride, ergot, etc., paralyzes vaso-motor (dilating) nerve-force, and the contractile power inherent in the muscular fibres of the arterial tubes, no longer restrained, asserts itself, contracting these vessels, moderating congestion, or arresting hemorrhage, etc. On the accepted vaso-motor theory we are required to believe, as Dr. Meryon asserts (*Rational Therap.*, p. 52), that aconite *stimulates* the vaso-motor nerves, "and by so doing diminishes the calibre of the arterioles." Is this a reasonable view of the action of so profound a paralyzer as aconite?

Take one example more. Dr. Burdon-Sanderson writes: "One of the effects of diminishing the proportion of oxygen in the circulating blood is to excite the vaso-motor centre, and thus determine contraction of the small arteries" (*Handbook*, p. 333). Now, is the condition of asphyxia thus produced really a process of stimulation to any part of the nervous system? Is such a condition favorable for the development of nerve-force, in excess of its normal production, to be thus expended in inducing contraction of arteries, which contract quite effectually (as we have seen) in the entire absence of nerve-power (*e. g.*) in death of the body. We have the boldness to claim that this asphyxiating process is a paralyzing one; that the vaso-motor centre is not excited, but depressed; and that what really occurs is paralysis of the (dilating) vaso motor nerves and unrestrained exercise of the contractile power of the arterial muscle, producing the vascular contraction referred to. In this state of asphyxia, in poisoning by aconite, in the collapse of cholera, and in death itself, we have uniformly contraction of the arteries under the control of the vaso-motor nerves. On one theory we are ex-

pected to find excitation of these nerves; on the other, paralysis in these several states. Which condition is it most natural and reasonable to expect to find?

Yours cordially,

THOMAS W. POOLE, M.D.

LINDSAY, ONT., CANADA, October 8, 1879.

THE "SUCCESSFUL PRACTITIONER" OF PINE RIDGE REVIEWED.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The Code of Medical Ethics is an acknowledged guide to physicians in their intercourse with each other, and with their patients and patrons. Experience has proven that where its teachings are honestly observed the result is alike beneficial to themselves and to their patients, but it is an observance of the *spirit* of the Code, as well as the letter, that produces these salutary results. I have seen, during a somewhat extensive and varied practice of medicine of many years, physicians who were confessedly great sticklers for the Code, but almost invariably, by word or deed, violated the *spirit* of that paper in every particular. To an honest, well-educated physician the Code is of no very great importance. He does *right* in all his dealings with his patients and patrons, and in all his relations with other physicians, and the Code teaches neither more nor less than this.

I am led to these reflections by reading an article that appeared in the *MEDICAL RECORD* of August the 30th, and continued in the number for September 13th, entitled "The Experiences of a Successful Practitioner."

This successful practitioner would have the readers of his article believe that he is a strict observer of the Code; and to this, and to his extreme kindness to his neighboring physicians, but more especially to the younger members of the profession, he attributes his success, and as an illustration of his honesty and fair dealing cites the case of Dr. White.

Now let us consider for a moment, how this "successful practitioner" observed the *spirit* of the Code in this very case he gives as a sample of his honesty. He says that one Sunday afternoon he was driving past Smith's, and was asked by Mrs. Smith to look at her son Harry. Although in a great hurry, having thirty (!) patients to visit before supper, he stepped in. He at once told the mother that her child was *very sick!* that it had evidently been left too long without proper treatment! Was this very first act in the drama *honest?* Was he warranted in giving the anxious mother this opinion, whether the patient was under the care of another physician or not, without a more careful examination of the case? He knew, or ought to have known upon what pathological conditions he based his opinion before giving it. In cases of "simple intestinal irritation," as this one turned out to be, there is usually no danger, and thus no necessity for grave looks or knowing glances; neither was there any cause for exciting the parents to fearful apprehensions as to the safety of their child. But having learned that Dr. White was treating the patient, he partially subsided, and advised them to send *at once* for Dr. White! Still, notwithstanding his great hurry and his *thirty* patients to visit before supper, he *took time* to inform them that he was a friend (!) of Dr. White, that the doctor was a good fellow—a very young man with little experience, but was willing to learn!—brought up a carpenter, and had studied medicine *two years*—when everybody knows that no medical college in this country con-

fers the degree of doctor of medicine until the applicant has studied medicine with some regular physician three full years. What more could this successful practitioner—this friend of Dr. White, have done to weaken the confidence of these people in the attending physician—and what more could the most consummate quack have done to secure the case? Admitting, for the sake of argument, that the "child was *very sick*," as he says—then this was a case of emergency, and in such cases, when a physician is called in to see a patient under the care of another physician, the Code allows him to prescribe such medicines as the emergency of the case requires—why, then, did not this friend of Dr. White, this strict observer of the Code! then and there give the child a dose of subnitrate of bismuth and oxalate of cerium, or his "chalk mixture well sweetened," to allay the vomiting, and then pass on and inform Dr. White, if convenient, of what he had done, without making so much ado about nothing? But it seems that this successful practitioner knew well what he was about. He had another object in view. He had aroused the fears of the parents for the safety of their child, and he had fully informed them of the opportunities and qualifications of Dr. White, and well he knew that these anxious parents would not allow this "very young doctor" to practise upon their Harry, and that they would not only call this "friend of Dr. White" in counsel, but that after a great display of his wisdom and his instruments (unnecessary in this case) he would get the patient to treat in the future. Well, it seems to have turned out just as he anticipated, and as every physician, without being a prophet, knew it would—for that very evening he was summoned by the father of the child to meet Dr. White in consultation.

Now, this honorable physician had, that very afternoon, seen the patient, and had given his opinion (although erroneous) in the case; and where was the necessity for taking along all his instruments, unless for display, and for the purpose of impressing upon the minds of the parents his superior abilities, and the ignorance of Dr. White? Every physician fully appreciates the necessity for the employment of all the instruments mentioned, in certain and very obscure cases; but who among us would deem it necessary to use an ophthalmoscope, a laryngoscope, an ear speculum, a stethoscope, a urinometer, etc., to diagnose a case of "simple intestinal irritation" that was cured in a few days by "chalk mixture well sweetened"? And Harry, too, must have been one of the best of boys to have submitted to such an examination, for every physician knows, who has had experience in the use of the laryngoscope, that it is very difficult, indeed, to employ it in the case of children, and never used unless there are urgent indications for its employment. Few children will allow an ear speculum to be introduced into their ears, even if it was suspected that there was "slight opacity of the tympanum due to thickening around the malleus, and slight œdema over the site of the tensor tympani muscle"! which condition would not be anticipated in "simple intestinal irritation." No wonder, then, that after this long and unnecessary examination of the patient, and after such a display of instruments and knowledge, that Dr. White's "position in that family was a little shaky;" and, although this friend had done his best, in accordance with the Code, to hold up his hands! the result was anything but pleasant to the aforesaid Dr. White.

The inquiry might here arise, does this "observer of the Code" make use of all these instruments with

each of his own patients? There certainly would be as much necessity for their employment as in the case of Harry, for medical aid would hardly be called to a case more simple or less dangerous than "simple intestinal irritation." It may be said, in answer to this inquiry, that he employed them at his first visit for the purpose of making out a *correct* diagnosis; but, if necessary at his first visit, they were certainly equally necessary at each subsequent visit, for he would naturally be anxious to know how those *fine points* he discovered in the case of Harry were getting along—such as "the choked disc," the thickening around the malleus, the tympanum, and that œdema over the site of the tensor tympani muscle; also that "slight paralysis" of the right vocal cord would need be seen to, as well as the cephalic temperature, which was increased, in Harry's case, $\frac{1}{100}$ of a degree! Then that umbilical ligament! should not be overlooked, to see if it had become abbreviated or elongated since his last visit. Then, again, those "slightly asphyxiated ascars vermiculares" should not be neglected; but, above all, as furnishing the key to the whole mystery, that "slightly elongated prepuce" needed close watching, especially where the case was of so much importance as that of "simple intestinal irritation"!

To have employed all these instruments in each of his own cases, it would take—let me see—we will add the time absolutely required for the use of each instrument, and just forty-two minutes are consumed with each patient—this time multiplied by thirty, the number of patients he was obliged to visit that afternoon before supper, and the conclusion is he must have had a very late supper! The whole story is a farce; and, whether written for the purpose of really showing his kindness to Dr. White, or whether to illustrate how miserably mean a physician can be to a young practitioner, under the guise of friendship and the *letter* of the Code, is difficult to determine. I mistrust the latter. However, such an article ought not to be allowed to go to the medical world without criticism, as it might, possibly, mislead some unthinking physician into a practice of the same tactics.

PARK CITY, UTAH TERRITORY, Oct. 4, 1879.

THE RAW-HIDE JACKET FOR SPINAL DISEASE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The discussion on the relative merits of the various mechanical supports for patients with Pott's disease, lately appearing in your journal and emphasized by your editorial review of the subject, leads me to call the attention of your readers to an apparatus not yet mentioned. It is, no doubt, known to many, but I believe not to the majority of the profession. I refer to the raw-hide jacket made by Mr. S. A. Darrach, of this city. Horse-hide, prepared so that it will neither wrinkle nor absorb moisture, is perforated and stretched over a plaster-cast of the patient's trunk. The mould for this cast is not made by a plaster-jacket as in the paper brace, but extension is made while the patient lies in a trough filled with plaster, and a thick layer of the same substance is placed over the abdomen and chest, after a piece of twine has been placed on the sides of the patient. After the plaster has set, the anterior segment is removed by cutting the mould by this twine from the axillæ to pelvis.

Any one who has applied the plaster bandage while the patient is suspended, will realize how much

discomfort and fatigue is saved by this method, and how much more accurate must be the fit. It is almost impossible to prevent a patient while suspended from drawing up a shoulder or hip, the tired and strained muscles involuntarily seeking some relief. This produces a slight wrinkling of the inside of the jacket, and is a frequent source of intolerance. This nearly inevitable wrinkling is noticed by Dr. Vance, who "smooths them off" before making his cast.

The raw-hide jacket seems to me to have nearly every advantage possessed by the plaster-jacket or steel brace, with several in addition. My experience of these supports, though limited to seven cases, has been carefully considered. In disease of the upper portion of the spine, a head-rest is attached to the hide jackets. In disease of lumbar vertebrae, I think a jointed steel support down the leg to the shoe adds much to its efficacy. Crutches are attached to all of these jackets. To sum up briefly the advantages and disadvantages of this means of support over the plaster jacket:

The latter are: 1. It cannot be applied by the physician, nor even by an ordinary instrument-maker. 2. The expense, \$40 to \$50.

The advantages are: 1. Durability. They can be worn until outgrown. 2. Lightness. 3. Ventilation through perforations. 4. Possibility of removal for bathing or examinations. 5. Its perfect smoothness, which makes abrasions impossible.

In conclusion, let me hope that the space you have given this subject will be the means of calling such attention to it that its symptoms may be more carefully studied and earlier recognized; that fewer erroneous diagnoses of rheumatism or muscular weakness be made, only to be corrected by the deformity which makes the true nature of the disease but too evident. It is not too much to believe that soon the vast army of hunchbacks walking our streets will receive few recruits—I may say no accessions. Of course there will be some subjects of this disease who, from constitutional taint, cannot recover; but those with enough vitality to convert the breaking-down process into a reparative one, after several vertebrae have been affected, certainly, with proper treatment, could early in the disease be cured without deformity. The physical suffering saved will be enormous, but who can estimate the mental distress prevented?

EMMA WARD EDWARDS, M.D.

NEWARK, N. J., Oct. 4, 1879.

New Instruments.

EAR AND THROAT CASE.

This case is intended for physicians in general practice who are constantly required to examine the ears and throats of patients, and do not need to equip themselves with every special ear and throat instrument in use.

It is generally found difficult to keep such instruments together so as to be available when wanted, and therefore, this pocket case, which contains every requisite for aural and laryngoscopic examinations, and which can be carried in the pocket, is recommended. It contains a concave reflecting mirror, with head-band, suited very well for either otoscopic or laryngoscopic examinations, and it should always be worn on the head when used, as both hands are thus left at liberty for manipulations. Ear specula, tongue-de-

pressor, and a small mirror for pharyngeal or laryngeal inspection, are contained in this case. The forceps are, if used with ordinary care, useful in dressing the ear or in the removal of foreign bodies. Two vulcanite cotton-wool carriers are provided, one for the ear and one for the throat. When one end of the carrier is wrapped tightly with absorbent cotton-wool, the end portion of the wool projecting in a brush-like form, it may be used in wiping out the auditory meatus so that an examination of the drum-head or tympanic cavity can be made without syringing the ear with water; and medicinal substances can also be carried by the brush to either ear or throat.

A compartment is provided for absorbent wool, and another for probes of silver, etc.

Mr. Ford, of the establishment of the Messrs. Caswell, Hazard & Co., has succeeded in arranging these instruments in a case of very small proportions, and although it is not intended to take the place of the specialist's armamentarium, it will serve a useful purpose, if, from its convenient size and inexpensiveness, it should be generally adopted, and thus encourage more frequent examinations of regions not infrequently affected by disease.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Oct. 12th to 18th, 1879.

HORTON, S. W., Major and Surgeon. To proceed from Omaha, Neb., to Rawlins, Wyo. T., and report in person to the Dept. Comd'r. S. O. 91, Dept. of the Platte, Oct. 11, 1879.

GIBSON, J. R., Major and Surgeon. At expiration of his present leave of absence, to report in person to the Comd'g General Dept. of the East for assignment to duty. S. O. 235, A. G. O., Oct. 13, 1879.

BROWN, H. E., Capt. and Asst. Surgeon. Leave of absence extended one month. S. O. 111, Div. of the Missouri, Oct. 13, 1879.

TAYLOR, M. K., Capt. and Asst. Surgeon. To accompany 2d detachment of the 4th Cavalry from Ft. Clark to Ft. Hays, Kans., and return to proper station upon completion of this duty. S. O. 211, C. S., Dept. of Texas.

VICKERY, R. S., Capt. and Asst. Surgeon. Assigned to duty at Fort D. A. Russell, Wyo. T. S. O. 92, Dept. of the Platte, Oct. 11, 1879.

MIDDLETON, P., Capt. and Asst. Surgeon. Assigned to temporary duty as Post Surgeon at the Post of San Antonio, Texas. S. O. 211, Dept. of Texas, Oct. 7, 1879.

KIMBALL, J. P., Capt. and Asst. Surgeon. Confirms order of Oct. 1, 1879, directing him to proceed to Rawlins, Wyo. T., for duty in the field. S. O. 91, C. S., Dept. of the Platte.

DE WITT, C., Capt. and Asst. Surgeon. Confirms order of Oct. 1, 1879, directing him to proceed to Rawlins, Wyo. T., for duty in the field. S. O. 91, C. S., Dept. of the Platte.

BYRNE, CHAS. B., Capt. and Asst. Surgeon. Relieved from duty in Dept. of Texas, to proceed to New York City, and on arrival report by letter to the Surgeon General. S. O. 235, C. S., A. G. O.

TURRILL, H. S., 1st Lieut. and Asst. Surgeon. Relieved from duty at Fort Columbus, N. Y. II., and assigned to duty at Madison Barracks, Sackett's Harbor, N. Y. S. O. 182, Dept. of the East, Oct. 16, 1879.

COMEGYS, E. T., 1st Lieut. and Asst. Surgeon. Relieved from operation of par. 7, S. O. 210, C. S., from these headquarters. S. O. 211, C. S., Dept. of Texas.

KILBOURNE, H. S., 1st Lieut. and Asst. Surgeon. To report in person to Comd'g General Dept. of the East for assignment to duty. S. O. 235, C. S., A. G. O.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 18, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Oct. 11, 1879...	0	14	36	3	21	33	0	0
Oct. 18, 1879...	0	10	31	3	48	31	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from October 15th to October 21st, inclusive, was 43, and the number of deaths that occurred was 23. The total number of cases for this year to October 22d is 1,522, and the total number of deaths, 540.

WEATHER STATISTICS.—THE EXTRAORDINARY HEAT OF THE PRESENT MONTH.—A close examination of the weather records, kept with great care at the Pennsylvania Hospital, Philadelphia (which extend back to the year 1825), show that within that time there has been no approach to the heat of the present month during any previous October. Since 1825 the warmest Octobers occurred during the years 1835 and 1861, but they bore no comparison to the present month. In October, 1835, the mean of the thermometer was 60 degrees, the maximum 78 degrees, and the minimum 42 degrees; the mercury rarely marking over 70 degrees. The mean of October, 1861, was 60 degrees, the maximum 85 degrees, and the minimum 38 degrees; but the mercury only rose to 80 degrees or over, three days in the entire month.

So far (18th) during the present month the thermometer has stood over 80 degrees on 11 different days, as follows: 1st, 88 degrees; 2d, 84 degrees; 3d, 87 degrees; 5th, 80 degrees; 6th, 80 degrees; 9th, 80 degrees; 10th, 80 degrees; 13th, 80 degrees; 15th, 83 degrees; 16th, 85 degrees; 17th, 83 degrees. The mercury has been over 70 degrees every day in the month so far except on the 5th; it has never at any time fallen lower than 55 degrees. Since 1825 the mercury has never risen higher than 87 degrees in October, except in the present month, and that was for one day in the month only. During October of last year the thermometer was 80 degrees and over on four different days, the average maximum being 66.58 degrees, and the average minimum 50.29 degrees.

Within the past 54 years prior to the present, the mercury has only marked 80 degrees or over during October of those years, 11 times, and then only from one to three days at a time; and it is, therefore, apparent that the present is the warmest October for at least 54 years.

DR. T. JULIUS LEMOYNE, the Father of Cremation in this country, is dead. Dr. Lemoyne was a retired physician, who had amassed a fortune, and who has during the past ten years been experimenting in cremation. He was of French descent, but born in this country in 1797. He graduated at Washington University in 1815, and at the University Medical College, Philadelphia, in 1820. Half a century ago he was Abolition candidate for Governor of Pennsylvania, and later, was candidate for Vice-President on the ticket with Gerrit Smith. He has lived at Washington, Pa., and it is there that his cremation furnace was built. This furnace was the result of much study, and was proved to be a success when three years ago Baron de Palm was incinerated in it. It has now satisfactorily consumed the remains of its originator.

Dr. Lemoyne was a large man, of fine presence, with a very long, silvery beard. He retained his mental faculties and his enthusiasm over cremation up to the last.

TYPHOID FEVER IN INFANCY AND CHILDHOOD.

A CLINICAL LECTURE DELIVERED IN BELLEVUE HOSPITAL,

By A. JACOBI, M.D.,

PROFESSOR OF DISEASES OF CHILDREN IN THE COLLEGE OF PHYSICIANS AND SURGEONS IN NEW YORK CITY.

(Reported for THE MEDICAL RECORD.)

PART II.

COMPLICATIONS OF TYPHOID FEVER.

GENTLEMEN:—Let us next study something of the complications of typhoid fever. Now and then you find *pneumonia* with it in the adult, and it is then chiefly hypostatic in character. In children it is more frequently *not* hypostatic in character. For most children sick with typhoid fever are not in bed to such an extent as are adults. Even, as you know, adults sick with typhoid fever will sometimes walk about during the entire course of the disease. Children may have bronchial catarrh to a certain extent, the same as adults. In the adult the bronchial catarrh does not generally lead into pneumonia. In children the case is different. In a large majority of cases, pneumonia occurring in children is of the lobular variety, and the immediate result of a bronchial catarrh; in other words, there is a *broncho-pneumonia*. The small branches of a bronchus become obstructed by viscid mucus, especially when the respiratory movements are not active, collapse of the lung sets in, hyperemia follows, and lobular pneumonia is developed. Thus it is why pneumonia is chiefly found toward the latter stage of typhoid fever in the adult, while it is not infrequently developed in the beginning or at an earlier period of the fever in children. While typhoid fever may be a very mild affair in childhood, this complication is frequently very severe. It is always well, therefore, to be upon the lookout for its occurrence, and never to be satisfied with a single examination. I came near being satisfied in this case here with the diagnosis of broncho-pneumonia, but a second examination prevented me from falling into that error.

Another complication which may be present is *meningeal hyperemia*. As soon as the functions of the muscles become reduced, especially those of the heart, which is particularly apt to occur in cases in which the fever is high, and consecutive granular degeneration takes place, you must expect less propelling power on the part of the heart, and then meningeal hyperemia is not infrequent in the brain and in the spinal cord. Now and then such children have a little obtuseness of hearing and slight twitchings. The spinal symptoms, as a rule, are not dangerous. The brain symptoms are dangerous, and, as a rule, they will be developed with the occurrence of high temperature. It is, therefore, of the utmost importance to reduce the high temperature as speedily as possible.

The complication with *diarrhoea* is not a frequent one. It is seen now and then in bad cases, but in the majority of cases it will be entirely absent. When it is present you have not always reason to suppose that there is ulceration of Peyer's patches.

For in the beginning there is extensive hyperemia,

with over-secretion only; in the later weeks diarrhoea means ulceration. On the other hand, however, the presence of intestinal ulcerations does not necessarily bring on diarrhoea in either the adult or the young, as might be supposed by those who study typhoid fever, as it appears with us, through European textbooks. In the Mount Sinai Hospital I lost a man from perforation of a typhoid ulceration, after a protracted illness, with never so much as a single attack of diarrhoea; and in Ward 28, Bellevue Hospital, a girl of ten years from the same cause, without a single loose passage during the whole course of the disease.

PROGNOSIS.

As a rule, in most cases of typhoid fever occurring in children, the disease runs a mild course. But few cases terminate fatally. When they do terminate fatally it is not usually the typhoid fever which kills, but the complication, and, therefore, it requires an attentive physician to pronounce the prognosis in such cases. In most cases it is the broncho-pneumonia, or the height of the fever, if the fever be high, which is dangerous. Pneumonia is always to be looked for. The large percentage of mortality which is reported in cases of typhoid fever treated in infant asylums from year to year may, in view of what I have said, surprise you. For instance, the mortality in typhoid fever in the Paris Hospital is large, and in every hospital it is always so. In private practice probably your mortality will not be more than one in ten or twenty, and in many epidemics very much less. But remember that there are cases in which all the symptoms of adult typhoid fever may be developed. In such the prognosis ought to be guarded indeed.

TREATMENT.

Typhoid fever in childhood must be considered as a very manageable disease, if taken in time. How is it to be taken? Remember that the danger in a disease which does not produce a great deal of anatomical change is found in its long duration and in the height of the fever. A low fever which lasts long will finally become dangerous by producing disintegration of tissue, if by nothing else, besides interfering with digestion. But high fever may prove dangerous in a very short time. When the temperature rises to 105° or 106° F. the baby may pass into a convulsion, and that convulsion may be a fatal one. In late years the high temperature has been extensively treated by the use of *cold water* in the form of *cold bathing*, *sponging*, and the *cold pack*. The treatment has commonly been to place the patient in a tepid-bath, which is reduced to a lower temperature by the gradual addition of ice or cold water, until the point desired is reached. The temperature of the body is reduced in this manner. In a few hours, sometimes within half an hour, the temperature may be just as high as it was before the bath was given. Now and then, the effect will last for four, five, or six hours. In order that a child may be safely bathed with cold water in this way it must have vitality enough to establish reaction; that is, as soon as the baby is wrapped up the surface must begin to become warm again. If it does not there is great danger, for you must recollect that the diminution of the temperature of the body takes place in large part from the skin. If the skin remains cool and the blood-vessels remain contracted, a very hot blood certainly cannot cool. In such cases where reaction was not readily established, I have introduced the thermometer into the rectum and found a high temperature. That condi-

tion of things is very dangerous indeed. Therefore, after having the child in a cold bath, if reaction was not at once established, I have sometimes reduced the temperature by plunging it into a hot bath, which has the effect of restoring the circulation on the surface of the body, and thus enabling the blood to throw off a part of its heat. In this manner I have seen a temperature of 106° F. in the rectum reduced within a few minutes to 102° F., or even lower. You will do well to be especially careful when the feet remain cold after a cold bath. When such is the case I consider the case none that will bear, or thrive on, the cold-water treatment; and I believe that in such cases you will do better to give up the cold bath entirely. As a rule, in such cases, washing the surface with cold water, down as far as the thighs, is sufficient.

Now and then the cold pack over the chest and the abdomen may be used with good results. In fact, it is preferable where reaction will but partly set in. Where, as in the above cases, the feet are apt not to recover their warmth speedily, cold packing of the trunk only is beneficial, not only in infectious, but also in inflammatory fevers. In the pack the child is to be retained until both pack and surface become slightly warm—provided this occurs soon; for, when a long time is required before reaction sets in—say twenty minutes or more—the pack and cold-water treatment are dangerous. When the body warms up within eight or ten minutes, the pack ought to be changed at once, and not remain until the body is quite warm again. In all cases, however, much depends on two things—firstly, on the general condition of the child, and secondly, on the intelligent watching of the little patient by both physician and nurse. Here, as everywhere, the Latin proverb holds good, that when two do the same thing, it is not always the same thing.

We also know that *quinine* reduces temperature, and therefore it is given when the temperature is high. Here again you are to remember, that this remedy is always to be used with a little care. Small doses of quinine will not reduce the temperature, and if the baby requires eight, ten, or fifteen grains daily, it should be given in one or two doses. If the temperature is very high, from twelve to sixteen grains may be given at a dose. But you have to be careful with reference to the size of the dose, for the quinine may not be digested at all. In general, in fevers, quinine is not readily digested, or readily dissolved in the stomach, so that it can be assimilated. Thus, when quinine is given, it should always be administered in solution, and the *muriate* is preferable to the sulphate, because the sulphate requires a great deal of water to dissolve it, while the muriate requires only a proportionately small quantity of water. If muriatic acid is added to the sulphate of quinine, of course it is made more soluble, but it is less likely to be well tolerated by the stomach. The taste of quinine is something which is disagreeable. One of the preparations which is most easily taken is the *neutral tannate of quinine*. It is not very soluble in water outside of the stomach, but it appears to have a very good effect. It contains about forty per cent. of the quinine contained in the sulphate, and therefore must be given in proportionately large doses; one grain of the sulphate being equal to two and a half of the neutral tannate. As this preparation was originally made, according to the old formula, it is almost absolutely insoluble, and therefore should not be given at all. Whatever preparation you may use, do not forget one rule which is set down as a positive fact, principally by Liebermeister. Now and

then it will happen that you cannot reduce the temperature at all by administering frequent doses during the day, say ten-grain doses to an adult three, four, five times a day, whereas by the administration of the whole quantity in one or two doses satisfactory results will be obtained. This is nothing absolutely new, for I said the same thing sixteen or eighteen years ago, and also published it, and at that time I was tabooed for it. I have, however, had the satisfaction since of knowing that those who then disliked my so called large doses of quinine have outdone me by far, and I have occasionally been startled at the size of the doses which my colleagues and my former pupils have not hesitated to employ.

Salicylic acid and the *salicylate of soda* are remedies which are used to reduce high temperature. I have already taken occasion to speak of these remedies some time ago, and in the treatment of the high temperature of typhoid fever they may do a great deal of good. I do not hesitate to recommend them in spite of what has been said with reference to salicylic acid producing a tendency to epistaxis and hemorrhages in general. It is true that now and then hemorrhages occur in cases in which there exists a predisposition, but we must not believe that every hemorrhage which takes place is due to the salicylic acid, for we know that in typhoid fever hemorrhages occur from the disease itself.

When you succeed in reducing the temperature in typhoid fever the game is half won. Therefore remember that the principal object is to diminish the body heat and make the patient comfortable. You cannot reduce the duration of the disease, it is true, but there is a vast difference between a typhoid fever which runs three or four weeks with a temperature of 104° or 105° F. and one which runs three weeks with a temperature of 101° or 102° F. A great many cases will not die of the disease, but of complications a number will die after convalescence has been established, and the more protracted the convalescence is, the more likely complications are to occur, whatever these complication may be. Salicylate of soda may be given to a child in doses of three or six grains, three, four, five times in the course of twenty-four hours, and it will occasionally reduce a high temperature which is not affected by quinine. I will here repeat what I have already said in another place, that when quinine does nothing, that when salicylic acid does nothing, the combination of the two remedies will sometimes give surprising results. These results I have verified both in private and in hospital practice.

Digitalis has been recommended. Now and then there may be an indication for its use in small doses, for the purpose of invigorating the heart's action.

Veratrum viride has been recommended for the same purpose, but I advise strongly against it, because its action is sedative, and sometimes it produces very disagreeable irritant effects upon the mucous membrane of the stomach and intestines, an effect which certainly you wish to avoid in no disease more than in typhoid fever.

Look after the patient's general condition. Now and then, even when there is not much fever, you may use *stimulants*, and if stimulants are indicated anywhere, it is in infectious diseases. There a baby of almost any age, from one year and over, may take an ounce of brandy or whiskey within twenty-four hours. It should never be given alone, for its action upon the physiological function of the stomach is disagreeable; therefore it should always be given in milk, or water, or barley-water, etc. In occasional cases, stronger stimulants, or a combination of stimulants, will be required.

Camphor is an excellent stimulant, and to a child two, three, or four years of age, you may give from two to ten grains of camphor every day for a number of days in succession. I believe that camphor has fallen into disrepute as a stimulant, because the doses given have not been sufficiently large. It has been recommended in pneumonia, and used to considerable extent; but is often replaced by carbonate of ammonia and other stimulants. Carbonate of ammonia is certainly a good stimulant, but one chief objection to it is that its effect is very temporary, and in order to secure its continued effect the doses must be repeated very frequently, whereas the effect produced by camphor is something more permanent. I have seen ten-grain doses of camphor given to a child less than two years old in collapse of pneumonia, and the child revived, and is yet alive. It requires, however, a prudent and courageous practitioner to give such doses in the face of the prejudice against large doses of the drug, and indeed, such large doses are only very seldom required.

Musk is another powerful stimulant, and perhaps the most powerful of all. It also has fallen into disrepute as a stimulant, perhaps, because the doses recommended have been too small. The remedy is quite expensive, and I have no doubt that because of its price the doses recommended have been smaller than they should be. To a child two years old, who is in collapse, requiring the use of a strong stimulant, never give less than one or two grains of musk, and repeat the dose every hour. You may give musk in such doses as will reach twenty-five grains in the course of twenty-four hours, if an efficient stimulant is required. In some cases the results obtained will be admirable when nothing else seems to produce any effect whatever. At the same time do not forget that when you wish to obtain a speedy effect you must not rely upon the stomach. Do not forget that the stomach of a person in such collapse as requires the use of strong stimulants does not digest, for the stomach is feeble, like the other organs, and absorption does not take place. In such cases you must resort to *subcutaneous injections* of ether, or brandy, or alcohol, or camphor, dissolved either in ether, or in oil, or brandy. But you must be sure when camphor is dissolved in oil, or ether, or brandy, that the solution is not too strong, for if it is, the ether or brandy will be absorbed within a very short time, and the camphor left remaining in the subcutaneous tissue. My first experience of that kind I had in connection with the subcutaneous injection of quinine. I once succeeded in making a solution so strong that three drops contained one grain of quinine, and I soon after used it for purposes of subcutaneous injection, administering ten grains at each dose. These doses were repeated some thirteen or fifteen times. The patient died. I made a post mortem examination, cut down upon the place where I had injected the quinine, and there it was, every particle of it. The water had been absorbed at once, and the result was that the quinine remained intact in the subcutaneous tissue. The same thing may occur with camphor, and you are not to forget that, if too strong a solution is used, the remedy may remain unabsorbed beneath the skin.

HEMORRHAGE FROM THE BOWELS.

What is to be done when hemorrhage occurs from ulcerations in the bowels, rare though it may be? I have seen such a case, and I treated it by the use of *opium arabicum*. As far as opium is concerned, it seems to be contraindicated in infectious diseases because of its sedative effect. In the last century there were some

authors who said that opium was a sedative, while others said that it was not a sedative at all, but an excitant. Then there was a war of opinion which lasted for about twenty years, and still the question was not entirely settled. From what is now known of the drug, I think the question concerning its effect can be readily answered. Opium administered in small doses is an excitant, but when given in large doses its effect is sedative. There are very many cases in which the effect produced by opium given in small doses is plainly a stimulant. For example: in a case of pneumonia and endocarditis which occurred in my service at the Mount Sinai Hospital, I wished to obtain the stimulating and the constipating effect at the same time. For the patient, an adult, had a great deal of diarrhoea at the same time, and I gave him one-fifteenth of a grain of opium every hour with a very beneficial result. The accumulation of the opium after a time arrested the diarrhoeal discharge, and, together with camphor and brandy, it acted as a stimulant, and the patient made a good rally.

Alum does good in cases of hemorrhage from the bowels, and is better than tannin, because it interferes less with digestion.

Hemorrhage will now and then be found in connection with a case of typhoid that has continued for a long time. I have seen one such case. It was in a boy six years of age. In that case I resorted to applications of ice. An ice-bag was kept constantly applied over the ileocecal valve, and at the same time a moderate amount of opium with a great deal of alum was given.

These are the principal points of importance in connection with the typhoid fever of infants and children. It was not my object to enter upon the study of the subject of typhoid fever in general, for that belongs within the domain of another clinic.

In regard to food, the first indication is this, that the digestive organs should not be overloaded, and that the food should be fluid. The second, that the patient should have enough nutriment. Both of these indications are valid for both the disease itself and convalescence. The intelligent practitioner will know how to deal with the individual case.

THE HISTORY OF AUSCULTATION.

AN ABSTRACT OF A LECTURE DELIVERED IN THE PRELIMINARY COURSE, 1879.

By JAMES T. WHITTAKER, M.A., M.D.,

PROF. THEORY AND PRACTICE OF MEDICINE IN THE MEDICAL COLLEGE OF OHIO.

GENTLEMEN:—The purpose of your coming here is, more especially, the education of the special senses for the detection of disease. Ambrose Paré wrote once a work entitled "Table méthodique pour cognoître les maladies par les cinq sens" (a Systematic Table for the Recognition of Disease by the Five Senses). In his day (1560) the use of one of these senses for this purpose, that of hearing, was little known. The physician heard, of course, the history of the patient, and thus of the disease, indirectly, but from an unskilled witness. With the discovery of auscultation the disease itself spoke directly to the ear of the educated physician. How much was thus added to the sum of our knowledge becomes apparent from a single statement. Before the discovery of auscultation, all diseases of the lungs (phthises, pleuritis, cancers, abscesses, etc.) were considered, in life, at least, as varieties of pneumonia. Since auscultation, we are able to dif-

erentiate varieties of pneumonia itself. The evidence offered by auscultation, in diseases of the chest, outranks in value that furnished by every other means of investigation. In many cases a diagnosis without it is absolutely impossible. In all cases it is the last and most effectual appeal.

But, before we engage upon the practical study of auscultation, we must say something of its history. A book, unless full of original work, which contains no reference to the past, is unworthy of preservation, and a course of lectures without some recital of the history of the subject is unfinished, and can make no permanent impression. A great French physician, Littré, once said: "It is the history of medicine which makes it a science instead of a trade." In fact, a subject without a history is as tame as a river without traditions.

The discovery of auscultation is an exception in the history of medical discoveries. Of most of them, it may be said, that were developed by evolution. By line upon line they are written. The final revelation to decipher and illumine the entire text is a natural and necessary sequence, and the period of its disclosure is a mere question of time. But it was different with auscultation. It came all at once. There was nothing known of it for thousands of years, when with the advent of one man it came. Auscultation was the creation of Laënnec. The value of it has been disputed, but never its authorship. Percussion, the sister of auscultation, was mature already when auscultation was born. Some mode of percussion had been practised since the time of Hippocrates. Preceding the publication of Laënnec in 1819, there are only intimations of the possibility of auscultation, and these have been hunted out of musty volumes only within the last few years. All the glory of auscultation belongs to René Théodore Hyacinthe Laënnec, and the history of it, like the history of a nation founded by a great king, is, in large measure, the history of an individual.

Laënnec would probably never have discovered auscultation, had he not been a pathologist first. It was at the time when clinicians were just beginning to look upon diseases as lesions of organs. Laënnec was looking at the lesions in the lungs after death. He was at work upon a classification of diseases based upon anatomical lesions, limiting himself, however, to diseases of the chest, which always seem to have had for him especial attraction. For eighteen years Laënnec worked in the field of pathological anatomy before the clinical fruits of it were ripe. Laënnec was born in a little country town, Quimper, of Brittany, in 1781. He was raised by his uncle, a physician at Nantes, and came to Paris to prosecute his studies very young. His first public allusion to his work was in 1815, when he called the attention of the Paris Academy to the value of auscultation in a case of hydrothorax which he presented. It is supposed from the character of this case that his first intimation of auscultation was derived from the old Hippocratic succession which has now fallen into disuse. But Laënnec had shown signs of talent long before this in works on Hippocrates and on entozoa.

It does not seem strange that auscultation of the lungs should have been discovered after, and in consequence of, auscultation of the heart. For the recognition of the tumultuous action of the heart had attracted the attention of even Hippocrates, and it was his custom, as it was the custom of all his followers, to put the hands over it, that is, to practise palpation, in diagnosis of its condition. It is established by his writings that Hippocrates even put his

ear upon the chest in his endeavor to recognize the condition of the heart. But with the exception of a record by a single observer, nothing more was written of auscultation up to the time of Laënnec.

Laënnec's friend, Bayle, who had recently written the best work extant on tuberculosis, had called his attention to the case with which the sounds of the heart might be recognized by the ear in cases where the hand might fail in appreciation of them on account of embonpoint or surface dropsy. Just such a case presented itself to Laënnec in the person of a young lady, and the reserve which this case imposed led him to roll up a piece of paper in the form of a cylinder, that he might practise mediate instead of immediate auscultation. To his great surprise, the sounds of the heart, instead of being diminished, were intensified. It now occurred to him to extend his observations to ascertain the state of the lungs, the voice, the pleura, and pericardium. This was the birth of auscultation. It was in 1816—Laënnec was just thirty-five years old. He worked with his new discovery three years, having been appointed in the meantime physician to the Hospital Necker, and then, 1819, he published the first edition of the work which has since immortalized his name. It is in two volumes, and is entitled "De l'auscultation médiate ou traité du diagnostic des maladies des poumons et du cœur fondé principalement sur ce nouveau moyen d'exploration."

In 1823 he established his clinic at the Charité; in 1826 he became Professor of the College of France, Professor of the Faculty of Medicine of Paris, member of the Academy, etc., and in the same year, in the act of publishing the second edition of his work, he fell a victim to the disease, phthisis, the recognition of which he had done more to establish than all his predecessors.

Laënnec's stethoscope was a curious piece of mechanism. It was a wooden cylinder, a foot and a half long and an inch and a half thick. It was perforated throughout its length by a canal one-fourth of an inch in diameter. The bottom of it was hollowed out like a funnel. For convenience of package it was made of two pieces screwed together in the middle.*

I show you here a dozen varieties of stethoscopes, solid and tubular, rigid and flexible, of wood, bone, hard rubber, and metal. None of them have any essential advantage over the original instrument of Laënnec, and, as we have since learned, no one of them is as good as none at all. For the *auditus eruditus*, the educated hearing, is not a question of mechanics, but of the perceptive faculties and the intellect.

Some vague references to auscultation have been discovered in the writings of Cælius Aurelianus on acute diseases, of Ambrose Paré in his "Table méthodique," etc. (*phénomènes perçus par l'ouïe*), of Quarin, and of Harvey; but the sole reference that merits notice, from the time of Hippocrates down, is a curious statement of Robert Hooke in 1680, recently exhumed by Tyndall.

"It is not impossible," said Hooke, "to discover the modes of motion and the action of bodies by the sound which they produce. As in a watch we may hear the stroke of the balance, the rotation of the wheels, the friction of the works, the shock of the

* Mons. A. Chereau relates, Arch. Gén. de Méd., July, 1879, that Laënnec's first device, after the paper roll, was a "tubular cylinder of gold-beater's skin, which he filled with air by means of a sputum, and of which the central opening was maintained by means of a support of pasteboard." The author speaks of having seen in his youth the first wooden instrument, and "in truth it had a size altogether useless and well adapted to terrify patients."

hammers, and many other sounds, may we not discover the movements which take place in the interior of bodies, animal, vegetable, or mineral, by the sound which they produce, recognize the works accomplished in the interior of the divers factories of the human body, and learn thus what are the instruments or the tools which functionate badly, at certain times, abnormally with others? . . . I feel the blood mount to my face, when I consider with what disdain the majority of men will receive what I am about to say; I have found more than encouragement in recognizing by experience that I could hear perfectly the strokes of the heart of man like an accustomed sound, the coming and going of gases in the intestines or in other small vessels, that I could distinguish the state of the lungs by the sound of the respiration, the rheum of the brain by the sniffling of the nose, the displacement of joints by the clicking, and the sensation of the movement of organs in displacing each other." I quote this passage second-hand from the "Traité de percussion et d'auscultation," by E. J. Woillez, Paris, 1879, p. 124. The words of the English author may therefore be somewhat different, though I repeat to you a literal translation; but the sense must be completely expressed. Not many of us would blush now to have been the first to recognize the possibility of auscultation of the heart and lungs.

Auscultation has had a wide range since its discovery by Laënnec. A new special sense was added to the recognition of disease. Attempt is now made to utilize it in every cavity and over every solid organ of the body. I need hardly more than mention the value of it in the diagnosis of anemia or of an aneurism. But nowhere has it furnished such brilliant disclosures as in the field of obstetrics. And here, strange to say, it gives evidence of more positive value than in diseases of the chest. For, as Skoda has so clearly shown—and this is the chief merit of his work—an auscultatory sign is not pathognomonic of any disease of the chest, as the old French authors taught. Any sign may be heard in almost any disease. An auscultatory sign means not a certain disease, but a certain condition of the lungs, a condition which may be produced by a great variety of diseases. Whereas, auscultation of the fetal heart means always, absolutely, beyond dispute, the existence of gestation and the life of the fœtus.

Mayor, of Geneva, first announced the recognition of the sound of the fetal heart in the *Bibliothèque Universelle de Genève*, vol. ix., November, 1818. Mavor was listening for active movements of the fœtus, with the head directly upon the abdomen of the mother, when his quick ear detected the finer movements of the fetal heart. It was a purely accidental discovery, but was not without its import to the Genevese physician. He even proposed to utilize its presence or absence to determine the life or death of the child. Like most of the discoveries of pure accident, however, the sound of the fetal heart did not impress its real discoverer with its full and varied significance. There was no mention of it further, and it was reserved for Kergardec, the friend and pupil of Laënnec, to rediscover it, and fix it as a fact forever. Kergardec's discovery, or rediscovery, was totally independent of, and without the knowledge of the previous publication of the physician of Geneva. It happened in the prosecution of studies with the stethoscope, then the novelty, and the discovery of his friend and preceptor, Laënnec. Kergardec was listening for a wave-sound—a motion of the waters by concussion from the limbs of the fœtus—which he failed to detect, of course, as there was no free space

or air by which sound could be produced; but it was while still listening for these impossible sounds, that there struck his ear the tic-tac of the fetal heart, which he recognized at once. Listening now for the fetal heart, he detected that other sound, the birth-right of whose discovery is indisputably his, viz., the sound of the uterine or utero-placental souffle.

The committee appointed by the Paris Academy reported favorably upon these sounds, and thus the discovery received at once scientific recognition. But there were not wanting objections to their value. Dugés and Baudeloque were not willing to accept them as diagnostic signs of pregnancy. Maygric claimed that they should be accepted as only corroborative signs, and Foderé maintained that the sound was too deceptive. But when Lenormand discovered the existence of a pregnancy in a case which had been treated for seven months for scirrhus of the right ovary, the objections all fell to the ground. Laënnec himself at once accepted the obstetric sounds in their full significance. In the second edition of his work he incorporated the "Mémoire sur l'auscultation appliquée à l'étude de la grossesse," read by Kergardec before the Royal Academy of Medicine, December, 1821, and declared that he had confirmed the truth of all its statements. Laënnec himself paid to the skill of Kergardec the highest compliment he could receive—a compliment keenly appreciated under the circumstances, as we may well understand—when he wrote "the study of the phenomena we are about to describe demands incomparably more attention than that of any connected with diseases of the chest."*

Of the varied significance of the fetal heart-sounds in determination of life, position, single or multiple fœtus, sex, etc., this is no place to speak. It is a chapter that belongs to the chair of obstetrics, where every instruction will be imparted; but I cannot refrain from noticing for one moment the meaning of it in determination of pregnancy itself. I have before me a work on obstetrics, published at Weimar in 1822, Froriep's well-known "Handbuch der Geburtshilfe," a text-book in its day in various schools. News travelled slowly fifty years ago. No mention whatever is made of the sounds of the fetal heart. Under the diagnosis of pregnancy are given many curious signs, thickness of the neck, for instance, from thyroid enlargement, increase in the size of the buttocks, etc.; these, of course, after cessation of the menses, changes in the mammae, cervix uteri, etc.; and finally, the author concludes, p. 186: "There is, therefore, no single absolute sign that alone and in all cases determines the existence of pregnancy, except the actual commencement of labor, dilatation of the os, and distinct palpation of the presenting parts of the fœtus." †

Since the days of Kergardec a skin disease is not easier to read than is pregnancy after the fourth or fifth month.

I think I need scarcely make an apology for this detail upon a part of the subject which strictly belongs to another chair. We are engaged with the history of auscultation in general. Obstetric auscultation was discovered and established by general clinicians, and is the most brilliant chapter in the whole book.

Auscultation in our day has ceased to be a novelty.

* "L'étude des phénomènes dont nous venons de parler dans cet article demande incomparablement plus d'attention que celle de tous ceux que présentent les maladies de la poitrine."—Vol. II., p. 406.

† Es gibt also kein einziges absolut sicheres Zeichen, was allein und in allen Fällen über das Dasein einer Schwangerschaft entscheiden kann, ausser den wirklichen Anfang der Geburtserreißung, wo die durch die Haut in dem geöffneten Muttermunde deutlich fühlbaren Theile des Kindes freilich keinen Zweifel mehr Raum lassen. P. 186.

The lustre of its value has been apparently dimmed by later aids to diagnosis. The microscope, ophthalmoscope, laryngoscope—above all, in our day, the aspirator—appear before the stethoscope. But it is only because of their novelty. The stethoscope remains the symbol of clinical medicine.

Original Communications.

HEAT IN THE TREATMENT OF FEVERS.

By FRANK ALLPORT, M.D.,

SYCAMORE, ILLINOIS.

AN enumeration of the many indications for the use of external heat in treating disease, together with the pathology of such affections, and the distinct evidences for its administration, would be incompatible with the aim and scope of this paper. My endeavor is simply to bring before the profession, some of the more important points, relative to the efficacy of external heat in battling with some pathological conditions, and to enter a plea for its more extended adoption.

When the opinion is advanced, that in the essential pyrexie this agent is most signally useful, the writer would not be misunderstood as conveying the idea, that here alone is benefit observable. Its administration is advantageous, under proper restrictions, in all diseases dependent upon internal congestion and deficient elimination.

The system is constantly undergoing the process of absorption, and that of elimination. Both are vital in their effects upon the animal organism. An individual may die of inanition, or may have the avenues of elimination so effectually disturbed, as to cause his demise. So accurately is the human frame constructed, that no one may enjoy perfect health unless each organ or organs of absorption and elimination, properly perform their functions. In case one means of casting off waste product becomes incapacitated, others endeavor to perform the work, and vicarious elimination is established. When one organ, or set of organs, thus assume the office of others, the additional labor is manifested in a corresponding degree of disease, in the overtaxed part. If the bowels or kidneys are impeded in action, and the tissues of the body become infiltrated with extraneous substances, a foul odor is observable in the exhalations from the skin, and lungs, and pathological conditions are the natural result. The human body contains 2,300,000 sweat-glands, from which nearly two pounds of perspiration should be lost daily. Let this amount be materially reduced, and the system quickly responds to the deleterious influences of the non-eliminated poisons, while the organs vicariously performing the skin's labor become correspondingly diseased.

In essential fevers, perhaps the most constant conditions are a variable amount of visceral congestion and a heightened temperature. The origin of the former is conjectural, but the latter is probably largely due to the non-elimination of effete products, occasioned by more or less inflammation in those organs elected for such work.

Physicians are lamentably prone to imperfectly distinguish between heat *proper*, and the factors producing it; at the same time, ascribing results, effects, etc., to the former, which should be attributed to the latter. For example, Liebermeister states in Ziemssen's

Cyclopedia, that "by far the greater number of those who succumb to typhoid fever, die from the effect, directly or indirectly, of the fever-heat." He also assigns the nervous symptoms of this disease to the same cause, and even, finally, goes so far as to consider death in typhoid fever, from whatever cause, as attributable to exalted temperature. A careful analysis of the conditions involved will, I think, convince one that the original difficulty is, as already stated, largely non-elimination. This it is which mainly aids in the generation of heat and the production of death. With these contingencies in view, a line of practice inducing vicarious elimination is indicated. Catharsis and diuresis are inadvisable, from a pre-existing irritability of those organs, acted upon by agents producing such effects. Profuse diaphoresis becomes, therefore, a desideratum, and for this purpose, nothing is so efficacious as the external application of heat. It opens the mouths of the tightly closed cutaneous pores, and liberates the perspiration loaded with the products of disease. Acting thus it becomes in the strictest sense an antipyretic.

Another agent of this character that has achieved great reputation, is the external application of cold. These two agents are apparently so diametrically opposite in their action, as to excite the inquiry, how both can be utilized in treating similar affections. In pursuance of this query, a brief analysis of the action of each will be made.

With cold, a shock is first produced, impelling the blood to the viscera, and closing the cutaneous pores. A reaction is soon expected, upon which the blood flows to the surface and relieves visceral congestion, a perspiration breaks forth, and the temperature is reduced. With heat, a subtraction of blood from visceral organs is first produced, simultaneously seeking the surface. The pores are opened. A quickly acquired profuse perspiration soon occurs, and as the system is emptied of the accumulated poisons the temperature falls.

I have said, in reference to cold, "a reaction is *expected*." Unfortunately this is not invariable, in which case death ensues, attributable to non-recovery from the shock. Reaction, therefore, accomplishes the benefit, by saving the patient's life from the first effect of the remedy. It is not, then, to the *immediate refrigerant action of cold* benefit must be ascribed, but to the powerful recoil of the system, from the shock produced by the application.

The antipyretic method of treating fevers is acknowledged, by those most capable of judging, as superior. Granting that cold and heat stand first in the category of such remedies, it remains to decide which of these, duly considering all things, should meet with the more approbation. At this juncture I will quote from the editor of the British Medical Journal and Prof. Liebermeister (both advocates of the cold bath), while speaking of this method of dealing with fevers. The former says: "The only contraindications to this treatment are, first of all, hemorrhage from the bowels in typhoid fever, even if it be present in the slightest degree. Perforation also precludes its continuance." The latter regards hemorrhage from the bowels as constituting one of the contraindications to the use of cold baths, and yet claims that this very complication is lessened in frequency by the use of cold. He says: "*It is possible that the determination of blood to the internal organs, caused by the abstraction of heat, may increase the tendency to hemorrhage.* The same thing, of course, holds true to a still greater degree in case of perforation of the bowels." Admission is here made that cold induces

a determination of blood to the internal organs. If this be true, and visceral congestion is one of the pathological conditions of typhoid fever, it would appear that any remedy aggravating this condition, would *always* be contra-indicated.

Liebermeister leaves the reader to infer, that a reduction of febrile action is expected when the surface of the body is cooled, and the internal organs congested, for he distinctly states, that abstraction of heat by the application of cold, induces a determination of blood to the viscera. This is strange philosophy, and would seem to indicate that the cutaneous surface is the most important seat of disease in typhoid fever.

The cold-water system is losing favor, and statistics from various hospitals, as stated by Dr. Peters, of Cohoes, N. Y., and others, indicate that it does not, in many instances, compare favorably with even expectant treatment. The hospitals in Vienna and Paris have declared against it. The mortality at Ulm, Stettin, Rheinau, and Ostprussen has been increased by it. Wunderlich, of Leipzig, reports a large percentage of deaths by this treatment, and Drs. Flamarion, Grimshaw, and Pepper hold the cold bath system in decided disrepute.

Liebermeister states, as the result of investigations in the hospitals at Basle, that there were, before the introduction of cold water, 7% per cent. of relapses, with two deaths. After the introduction, 9% per cent., with ten deaths.

Notwithstanding he attempts to explain away this unfavorable comparison, it is conceded that the cold bath treatment probably increases relapses, and he says: "If relapses are more frequent under antipyretic treatment, it seems natural to conclude that this treatment in so far interferes with the normal course of the disease as to retard the development, destruction, or expulsion of the poison as a whole, or entirely to prevent these changes in a certain portion of the poison." These investigations, etc., have induced Liebermeister to confess that he does not regard cold bathing as the remedy *par excellence* in typhoid fever; in fact, he observes that, "If I were forced to the unpleasant alternative of adopting only one or the other of these two remedies (cold water or quinine), I should, in the majority of cases, choose the latter."

Biermer and Lindwarm consider that this treatment increases relapses, and Shultz states: "It causes a considerable increase of hemorrhages by 4% per cent." He also says: "The different forms of delirium and complications are much increased." Lichtenstein asserts that he has observed 1,960 cold baths in typhoid fever, and that in 380 of these the temperature of the body was as high two hours after the baths as before, and *sometimes higher*.

Another argument against the cold bath is that too careful watching is required. Dr. Albutt, of England, an advocate of this system, says: "I would urge the continued presence of a medical man. The whole treatment must be managed with the utmost precision, and all tendencies to shiver or syncope should be watched by a skilful observer, or *irreparable damage may be done in five minutes*." Is it proper to continue the use of this remedy, so potent for evil, when we have in heat an agent both superior and less dangerous?

A comparison of the reduction of temperature produced respectively by the application of cold or heat, shows the former as more decided in its action. Dr. Beal cites cases from the practice of Dr. Wilson Fox, where the temperature was reduced, by a single immersion, eleven degrees. The reduction by heat has

never, so far as I can learn, equalled this by several degrees. This might at first be deemed evidence favorable to cold; on the contrary, it is antagonistic to it. There can be no doubt that such rapid and eccentric changes are usually of positive injury. It must be remembered that, after a reduction, a counteraction occurs, and the thermometer will soon register a rise in degrees, which may equal, and even exceed, that previously lost. Such decided and sudden vacillations are surely pernicious. What we require is a gradual but positive declination of temperature, such as obtains with the proper application of heat. Dr. Albutt states that a too rapid diminution of temperature is positively injurious in fevers. With this idea in mind, he endeavors, while still clinging to the cold bath, to somewhat modify its application, in order that so rapid a diminution may not be produced.

Neither heat nor cold is a specific in fevers. The benefit they accomplish is performed through profuse diaphoresis, by vicariously eliminating the manufactured, but imperfectly excreted poisons, thus relieving visceral congestion, and placing the system in a better condition to withstand the deleterious effects of the fever. My claim is, that heat accomplishes the desired result *better than cold*, and with far less danger.

In conclusion, I would beg leave to reply, very briefly, to Dr. Cowling's criticism (RECORD, Sept. 13, 1879) of my article on yellow fever, appearing in the RECORD of Aug. 16, 1879. He sees no analogy between Dr. Leard's experiments, and the applicability of the Turkish bath in yellow fever. The experiments referred to proved by ophthalmoscopic examination that internal congestion was lessened by the external application of heat. Granting this, and that visceral congestion is among the most important pathological conditions of yellow fever, how is it possible he can see no analogy between the experiments and this treatment of the disease?

Dr. Cowling says: "In yellow fever the blood is frequently thick and sluggish, having apparently lost its more fluid parts, and excessive sweating is not likely to replace it." May not this sluggish condition arise from an accumulation of eliminatory substances, as well as from loss of water? In cholera the condition of the blood is dense and viscid; and yet it is observed that the use of jaborandi, and the consequent excessive diaphoresis, is meeting with great success in treating this disease at Yokohama.

Dr. Cowling remarks that he is able to cite cases where excessive sweating was a factor in producing death in yellow fever. In these instances, it is possible that heat may not have been applied properly, or sufficient care may not have been observed in protecting the patient after the application.

If space allowed, reports might be adduced, where the external application of heat has proved highly advantageous in treating this disease in South America and elsewhere.

In the brief analyses just made it will be observed that with cold, shock, visceral congestion, and closure of the cutaneous pores, are first produced; but with heat no shock nor visceral congestion occur, and sweating is usually the primary result attained.

The University of Edinburgh has presented the Cameron prize, established to encourage studies in therapeutics, to Mr. Paul Bert, for his discovery of the value of compressed protoxide of nitrogen as an anæsthetic of long duration.

ELECTRICITY A PARALYZING AGENT.

By THOS. W. POOLE, M.D., M.C.P. & S., ONT.,

AUTHOR OF "PHYSIOLOGICAL THERAPEUTICS."

AMONG the standard writers on medical electricity this agent is regarded as an "alterative," a "tonic," and a "stimulant;" while by some it is said to possess these qualities in combination. Experimental physiologists invariably regard it as an "excitant," or "irritant" to nerve-tissue, and interpret the effects produced in accordance with this view of its action. It may be thought very bold in us to call in question opinions so generally received; but as we are persuaded the view of the action of electricity we are about to present is well founded, and especially as we shall appeal to the recognized authorities themselves in support of our thesis, we ask for it a fair and candid hearing.

We assert that electricity is a paralyzer of nerve-tissue, and we claim that all the effects it produces, as employed for therapeutical and physiological purposes, may be readily accounted for on this view of its action. In proof of its paralyzing effects on nerve-tissue, we point, first, to Matteucci's experiment on the spinal cord of a living rabbit, in which it was shown that during the passage of a common galvanic current the cord might be pricked, cut, torn, burned, or otherwise injured, without eliciting from the animal any sign of pain. Dr. C. B. Radcliffe, F.R.S., quotes this experiment (with others) in his "Lectures on Epilepsy, Paralysis, and Pain," and there distinctly asserts "the paralyzing influence" of electricity: "Whether the current was passed up the spine or down the spine, the result was the same so far as its paralyzing action was concerned, and so it was in the other two experiments which have been mentioned" (p. 65). Dr. Radcliffe, however, asserts that the muscles, as well as the nerves, are paralyzed by the galvanic current, to which, as well as to some other of his conclusions, we take exception, for reasons which will hereafter appear. Drs. Beard and Rockwell, leading medical electricians of New York, also testify to the same effect in stating that "the cord remains insensible to any stimulus that may be applied to it, so long as the current is passing." (Med. and Surg. Elec., 2d ed., p. 127). Dr. Moritz Meyer refers to the observations of Valentine, Matteucci, and Eckhard in this connection, and to the effects of the constant current on nerve-tissue, and adds: "In other words, the nerve is paralyzed so long as any portion of it is subjected to the action of a continuous current" (Elec. in Prac. Med. (Hammond), p. 62).

The faradic current produces similar paralyzing effects, which differ from those of the galvanic current "mainly in degree." Thus the faradic current has been effectually employed to benumb local sensation in parts about to be subjected to minor surgical operations, and, as is well known, both currents are employed for the temporary relief of neuralgia and other painful states; for which result no better explanation can be offered than that the nerves of the affected part are for the time so paralyzed as to render them incapable of transmitting the sensation of pain. It may be said that this effect is properly anesthesia rather than paralysis; but these are only different names for the same condition, and as Dr. Anstie has fully shown, anesthetics are invariably paralyzers (Stim. and Narcot., pp. 273, 323, 398, etc.) Electricians frequently allude to "the numbing effects" of electricity, including both the galvanic and faradic currents (Drs. Beard and Rock-

well, loc cit., pp. 122, 123). When the functional activity of a nerve is not simply perverted, but arrested, it may with propriety be said to be paralyzed, and the agent producing this effect is certainly not entitled to be called a stimulant, or its action that of an "excitant," as has been so much the rule in regard to electricity.

It is important here to note, as negative evidence of the truth of our proposition, that Prof. Trowbridge, of Harvard College, U. S., has demonstrated that the supposed natural currents of electricity, believed by Matteucci and Du Bois-Reymond to be present in nerve and muscle in repose, do not exist; but that the perturbations of the index of the galvanometer witnessed by them really depended upon currents developed in the galvanic accessories of the experiment, and not in the nerves or muscles themselves;* so that, so far as known, electricity plays no part whatever in the inter-relations of nerve and muscle. Nor is electricity known to be generated at all in the bodies of men and animals, since even in the case of certain electric fishes, which display a remarkable use of this agent, the electricity which they discharge may be simply induced in them by the opposite electricity of the media surrounding them, as appears to be probably the case in certain men and women who give out sparks of electricity—a condition largely dependent on the electric state of the atmosphere, that of their surroundings, and their own peculiar electric relations to these. It is true that electricity is found on the surface of animal and other bodies, in the static form, in which, so far as is known, it is inoperative and exerts no influence on vital processes, as the negative result of "charging" the surface of the body with electricity on an insulated stool serves as an illustration. In view of the present state of knowledge on this subject, those who assert that natural electricity plays any part in the vital operations of the living organism will have to begin anew the task of eliciting evidence in support of that doctrine.

Turning now again to the subject of artificial electricity, the question at once arises, If this agent be a paralyzer of nerve-tissue, how does it "stimulate" the muscles to contract in the manner so commonly witnessed? The reply to this inquiry involves an issue which we have attempted to discuss at length, in a recently published work, entitled "Physiological Therapeutics," and at which we can only glance in the space available here.

We are convinced that the nerves do not "stimulate" the muscles to contract. We find all the physiologists asserting the inherent contractile power of muscular fibre, and even admitting the ability of muscle to exercise this power, in many instances, quite independently of nervous influence. Illustrations of this are to be found in the movements of microscopic portions of protoplasm; in the contractions of the fetal heart before the development of nerves; in rhythmic and other movements of muscular parts after death of the body; in post-mortem parturition in pregnant females who had died undelivered at or near the end of the period of gestation; in parturition normally occurring in cases where the spinal cord had been destroyed by disease, or paralyzed previously, well authenticated cases of which are mentioned by Dr. W. B. Carpenter (Human Physiology, 5th Am. ed., pp. 979, 980); in the existence of rigor mortis, the facts of which have not been explained on any satisfactory basis (not excepting the latest hypothesis,

* Amer. Journ. of Science and Arts, May, 1872. Drs. Beard and Rockwell's Med. and Surg. Elec., 2d ed., pp. 108-111.

which refers it to conglutination of the myosin or muscle plasma), other than that of independent muscular contraction, which is the view of the late Dr. Anstie and of physiologists generally.

Dr. C. B. Radcliffe, in the work already quoted, asserts (in support of a different thesis) that "muscles do not pass into a state of contraction when they may be supposed to receive a larger supply of nervous influence than usual;" and, again, that "ordinary muscular contraction is associated with deprivation of nervous influence;" nay, more, "that the power of muscular contraction is inversely related to the amount of nervous influence supplied to the muscles from the nervous centres" (pp. 95-100). The experiments of Sir A. Cooper, Kussmaul and Tenner, and Dr. Brown-Séquard, are quoted in support of these propositions, which find additional confirmation in such facts as the cure of a much larger percentage of cases of tetanus by stimulants than by any other means (Dr. W. A. Hammond, *Diseases of Nerv. Syst.*, 540). It is only on the view that in the excessive muscular contraction here witnessed nerve-force was in abeyance (and not in excess) that stimulants could be justifiable, or this result explained. Dr. Anstie was so impressed with the force of Dr. Radcliffe's argument that after referring to it he writes: "The true action of vital force would appear to be rather that of restraining muscular contraction than of exciting it" (*Stim. and Narcot.*, p. 70).

Although Dr. Anstie does not appear to have further supported the opinion just quoted, it is certainly the view of the relations of nerve to muscle most consistent with the facts. It would really appear that whatever cause paralyzes nerve-force sets the muscle free to assert its inherent contractile power, and it does this with clonic or tonic results in proportion to its freedom.

Electricity paralyzes the motor nerves, and so permits muscular contraction. This principle, like a master-key, unlocks the fastnesses and clears up the obscure and hitherto unexplained problems in electrical treatment. It accounts for the benefit this agent sometimes affords to muscles suffering from enforced disuse, by the exercise it gives them, thus attracting blood, and with this pabulum, whereby their nutrition is improved. It accounts for the failure of electricity in chorea (Dr. J. Russell Reynolds, *Clin. Uses, etc.*, p. 83) and in spasmodic states generally. Why this failure? Because the preponderance of muscular action here is owing to the too feeble restraint already exercised by weak or exhausted nerves, and an additional paralyzing agent is the least likely means to benefit them. It explains why electricity is powerless for good whenever, as in early and late rigidity, it fails to induce muscular contraction; because the muscle is already isolated from the nervous centre; the nerve is paralyzed and electricity can paralyze it no further; the muscle is already freed from nervous restraint, and as electricity can free it no further it fails to cause it to contract, and its use can do no good, but may do much harm. It also serves to explain why it is, "if you find, for instance, a limb perfectly paralyzed, but contracting perfectly well to galvanism, or sometimes acting even in excess, you can do nothing more by applying galvanism to that limb" (Dr. J. Russell Reynolds, *Clin. Uses of Elec.*, p. 94). The benefits of electricity are for the muscle, in the manner already stated, but here the muscles are healthy and their condition cannot be improved. It is the nerve that is at fault, and electricity not being a tonic, or stimulant, or vitalizer to it, does not improve its condition, as it ought to do if it possessed the qualities attributed to

it. Here is a problem: "Why the muscles that are paralyzed should act more readily than healthy muscles to a slowly interrupted current has not yet been explained" (ib., p. 98). The explanation is easy. A weaker current serves to paralyze the nerves of the diseased limb, and set the muscles free to contract, than will suffice for the healthy nerves of the sound limb. Why a slowly interrupted galvanic current is sometimes effective for this purpose, where the faradic current fails, we have discussed elsewhere in our "Physiological Therapeutics," where the more important objections to the theory here advocated have also been considered.

Numerous facts might be adduced to show that the relations here assigned to motor nerve and muscle, apply also to the vaso-motor nerves and muscular coats of the arterioles. But as this part of the subject is only indirectly associated with the topic of this paper, and as we have discussed it in a recent issue of the *RECORD*, under the title of "The Effect of Pithing on the Vascular System," we make no further reference to it here.

We have already shown, how, as a paralyzing agent, electricity indirectly benefits muscles whose functional power is impaired from atrophy or disuse,—by improving their nutrition. A wide field of usefulness is also open to this agent—on the same view of its action as a nerve-paralyzer—in the control it exercises over vascular activity in organs and tissues. By paralyzing the vaso-motor nerves (whose function we claim to be to dilate the arterioles) it brings into play the independent contractile power of the muscular tissue of the arterial coats, and thus produces a reduction in the calibre of these vessels, arresting congestion and diminishing blood-supply to morbid growths or hypertrophied tissues, with the gratifying results not unfrequently recorded. Thus the undoubted beneficial results of electricity in certain cases, as well as its failure in others, find a ready explanation in the theory we advocate.

The present physiological theory of the action of electricity in arresting the heart is of a most extraordinary character. Faradization of the sinus venosus of the heart of the frog, at its junction with the auricle, brings the heart to a standstill. In order to account for the arrest of the heart by a reputed "stimulus," it was necessary to assume that it is a hypothetical "inhibitory" ganglion, which is thus excited so as to overpower the motor ganglia of the heart, and cause it to stop, and at the same time that the proper motor ganglia of the heart escape the "excitation" of the faradic current altogether.

Now, the chief motor ganglion of the heart of the frog is said by physiologists to be situated in the sinus referred to, close to the auricle, at the very point to which they apply the faradic current to arrest the heart. Why the motor ganglion, to which the current is thus directly applied, should be regarded as uninfluenced, while another ganglion, a little farther off in the septum, should be "excited" (though less directly in the range of the current), so as to master its reputed rivals and stop the heart, is a problem which requires explanation. We claim that the application of a faradic current to the chief motor ganglion of the heart paralyzes it directly, and so stops the heart; and further, in a paper in recent issues of the *Canada Lancet*, we have undertaken to show on physiological authority, that the so-called "inhibitory," "accelerator," and "depressor" nerves of the heart do not discharge the functions these names imply; that they do not directly influence the heart at all, and, so far as they influence it indirectly,

they do so through "the peripheral circulation" in the manner of ordinary vaso-motor nerves.

We desire to refer briefly to the serious consequences which may, and have, resulted in practice from the mistaken idea that electricity is a tonic or stimulant. We refer especially to its use as a supposed restorative in cases of suspended animation, as in apparent drowning, or in threatened death from chloroform. The cases on record where apparent benefit has resulted from electricity in these states, are so few, so associated with other remedial processes, and generally so unsatisfactory, as to furnish no trustworthy evidence in its favor, while that to the contrary is direct and convincing. It has notably failed in experiments where these states were artificially produced to test its powers, in the hands of such experienced electricians as Drs. Beard and Rockwell (*Med. and Surg. Elec.*, 2d ed., pp. 665-6). It has extinguished the spark of life in cases of threatened death, which were happily recovering under other means; and many more such catastrophes would be on record, if duly reported, and if it were not that batteries are frequently not available on such occasions—or when so, are often out of order, and fail to act.

Dr. Ringer, in writing of the use of electricity in these cases, states that "some authorities are wholly opposed to its use, on the score of its influence to arrest a very feebly beating heart, and so diminishing any slight remaining chances of recovery" (*Therapeutics*, p. 292). Dr. B. W. Richardson, of London, England, writing of resuscitation from the narcotism of chloroform artificially induced, states: "I feel it too unreasonable to recommend galvanic action as a means of resuscitation. Galvanism is a two-edged sword. It might by accident, I may say, in some cases, restart respiration, but it would in this respect be inferior in principle to artificial respiration, and in the majority of cases it would more effectually promote death than restore life. . . . When used as it is commonly used, merely to excite prolonged contraction of muscles, it is not aimless merely, but positively mischievous." Having narcotized a rabbit with chloroform till respiration and other evidences of life had ceased, and restored it by artificial respiration, he narcotized another to a similar degree, to show the effects of electricity. Commenting on the fatal result, he states: "When I used the electric stimulus [observe the word employed in this connection], I took out of the muscles what remaining force was there—the primary force required for recovery—and under the semblance of restoring life, clenched death!" (*Medical Times and Gazette*, 1870. *Braith. Retros.*, January, 1871, p. 256.)

How well this tallies with the action of electricity as a paralyser, and how very inconsistent it is with its action as a reputed stimulus! Yet such is the force of habit, custom, or blind adherence to authority, that men call that a stimulus while in the very act of recording its paralyzing effects. Nor is Dr. Richardson happy in his allusion to taking the force out of the muscles. The muscle is not paralyzed by electricity. It will soon pass into rigor mortis, in which it will display "the most steady and persistent contraction which muscle can possibly exhibit," to use the words of Dr. Anstie, a condition which electricity simply hastens. If Dr. R. had stated that by means of the electric current he had intensified the already existing paralysis of the nerves (produced by the chloroform), and thus prevented all chance of recovery, his statement would have been more in accord with his facts, and with the ideas he evidently intended to convey. Let us be courageous, and call a

spade a spade. "A rose by any other name would smell as sweet," but it is highly dangerous to label certain paralyzers roses—or stimuli—and proceed to employ them accordingly.

This fatal error has warped the whole course of physiological research, and given rise to the most absurd and contradictory statements in therapeutics. As an example, we are told by Preyer that "belladonna paralyzes the peripheral branches of the vagus and at the same time stimulates the nervous centres of respiration."

The fundamental error regarding electricity is responsible for this statement of contrarieties. Here is the process by which such a conclusion is reached. Electricity is said to be a stimulus. But it stops the heart. Then it must be assumed to excite (not the heart's motor ganglia, which would urge it faster, but) a nervous rival antagonistic to the motor ganglia. Hence the assumption of the "inhibitory" mechanism, which, so to say, is supposed to apply the brakes to the heart's motor ganglia. It follows from this, that to urge the heart to increased action we must stimulate its motor ganglia; to arrest it, we excite the inhibitory nerves. The action of drugs is interpreted according as they seem to act in one or other of these ways. Belladonna quickens the heart's action (under certain conditions). Hence it is said to paralyze the inhibitory ganglia (Dr. Ott) and also to paralyze "the peripheral branches of the vagus," which are understood to be connected with the inhibitory centre in the heart. By another chain of reasoning it is concluded that it excites the vagus at its origin.

It is pertinent here to inquire how the heart's motor ganglia escape the effects of the drug which is assumed to paralyze their rival? They are in proximity, in the same organ, fed by the same blood-stream, and yet one is held to be uninfluenced while the other is paralyzed. Again, Dr. Carpenter states that the membranous sheath of nerve-fibres "is not penetrated by blood-vessels." How then can the "branches" of a nerve-trunk be influenced by poisoned or medicated blood, except by impressions made on the nerve-centre and transmitted along the trunk? And if this be true physiology, how can a nerve centre and its trunk, or "branches," be in opposite conditions of excitation or paralysis? Is it not preferable to believe with Dr. Anstie that the action of narcotics "is an uniform one, and tends entirely in the direction of nervous death?"

A recent physiological author writes of belladonna: "It paralyzes the motor nerves of frogs, at the same time that it excites the spinal cord; after they recover from the motor paralysis, the tetanic symptoms of spinal stimulation appear" (Dr. Ott, *Action of Drugs*, p. 138). Is it by such teachings as this that we can ever learn the true action of drugs? Surely the hypothetical "Philadelphia lawyer," who is reputed able to solve all difficulties, has been at work here, preparing "a case" for the veritable Philadelphia doctor! But seriously, the inferences drawn from electrical experimentation, as to the functions of organs, when applied to the observed effects of drugs on these functions, have led even eminent writers into many such absurdities.

Electrical experimentation has borne a very prominent part in formulating the current views of the functions of certain parts of the organism, and has assisted in building up a very complex theory both of these functional activities and of the action of drugs in relation to them. A recognition of the true action of electricity as a paralyser, instead of as a stimulus to nerve-tissue, would, we believe, be a great gain to both physiology and therapeutics.

LINDSAY, ONT., CANADA, OCT. 8, 1879.

Reports of Hospitals.

METROPOLITAN THROAT HOSPITAL.

SERVICE OF DR. CLINTON WAGNER.

CASES OF INTRA-LARYNGEAL GROWTHS—OPERATIONS AND RESULTS.

(Reported by H. H. HOWLAND, M.D.)

CASE I.—Geo. S.—, aged six years, a frail, delicate child, extremely emaciated, was brought by his parents to the Metropolitan Throat Hospital, on February 2, 1879, for hoarseness, difficult breathing, and frequent attacks of spasm of the glottis, especially at night. His father stated that he had had several attacks of croup. The hoarseness and difficult breathing appeared shortly after last attack, nearly eighteen months ago. A laryngoscopic examination revealed a large papillomatous growth covering a greater portion of both cords anteriorly. Abduction of the cords was prevented by a web of false membrane, evidently the result of the attacks of croup, which left an opening posteriorly for the passage of air, scarcely larger than a pigeon quill. The extreme dyspnoea, with tendency to spasm of the glottis, the large size of the papilloma, and the presence of the false membrane, rendered an operation by the mouth impossible, and even the attempt Dr. Wagner considered imprudent and inadvisable. He was kept under observation a few days, during which time the dyspnoea increased, and the spasms of the glottis became more severe and more frequent. On February 9th, tracheotomy and thyrotomy were performed. The incision was carried down through the crico-thyroid membrane, but the cricoid was not divided. The growth and false membrane were thoroughly removed. A microscopic examination of the specimens by Dr. W. T. Alexander showed that the growth was a true papilloma, and the membrane of a false or adventitious character. Considerable irritative fever followed the operation, temperature at one time reaching 105° F., but under the careful administration of stimulants and nourishing diet he recovered. The tube was removed March 16th, and on March 30th, the external wounds having closed and healed, he was discharged cured. On April 26th he returned for examination, breathing excellent, voice improving, and had gained upwards of twenty pounds. He was again seen the latter part of August, and condition excellent.

CASE II.—Mrs. R.—, aged 24; native of Germany; occupation washing. Consulted Dr. Clinton Wagner at the Metropolitan Throat Hospital, July 6, 1878, for hoarseness. She had been hoarse for over a year, and when examined was almost completely aphonic. A laryngoscopic examination showed vocal cords relaxed, and small outgrowths at junction of anterior and middle third, preventing perfect approximation of cords. In these cases instrumental interference cannot be resorted to on account of the small size of the growths, and of their thorough incorporation with the tissues of the cords; but good results will frequently follow by the persistent application of the following formula of iodine: Iodine, gr. iij.; potassii iodidi, gr. vi.; glyce., ℥i., or zinci chloridi, gr. xv. to water, ℥i. In this case the above formula of iodine was used twice a week, and in March, 1879, the nodules had entirely disappeared and voice perfect.

CASE III.—Mrs. S.—, aged 32, native of America; occupation, sewing. Consulted Dr. Clinton Wagner at

the Metropolitan Throat Hospital, October 22, 1878, for hoarseness. Had been hoarse for over five years. A laryngoscopic examination showed a small papillomatous growth on superior surface of left vocal cord, overlapping free edge and near the anterior commissure. On November 11, 1878, Dr. Wagner removed the growth with Mackenzie's forceps. On March 10, 1879, patient revisited hospital. On examination, vocal cords normal and voice perfect.

CASE IV.—Jennie M.—, occupation singer, who had a large papilloma on each cord, and which were removed by Dr. Wagner, April 3, 1878, and reported by him in a paper on Intra-Laryngeal Growths (*Medical and Surgical Reporter*, Columbus, Ohio), Case V. Revisited the Hospital May 8, 1879, thirteen months after operation. On examination, not the slightest trace of growth visible, and a good singing voice.

Progress of Medical Science.

VOMITING OF PREGNANCY.—Fresh evidence of the value of Copeman's method of treating obstinate vomiting in pregnancy is proffered by Dr. Baldwin, of Columbus, Ohio. All the usual remedies had been tried in vain in a case under his care; even nitrate of silver to the os, which seemed to be specially indicated by the existence of erosions, had proved useless. The cervix was then freely dilated with the index finger, with immediate and most gratifying results. The vomiting, which for two weeks had been almost continuous, ceased as by magic, and in a few days the patient was about the house doing her work. The improvement was permanent, no relapse occurring.—*The Ohio Medical Recorder*, August, 1879.

CARBOLIC ACID IN MALARIAL DISEASE.—A strong plea for the value of carbolic acid in malarial disease is published from the pen of Dr. A. G. Tebault. He says: "As a prophylactic, carbolic acid given in grain doses, at intervals of three to six hours, has, in my hands, yielded comparatively far happier results, even in cases where unmistakable prodromata of malarial fever were actually present. In experiments instituted during the past seven years on my own person and others, feelings of lassitude, malaise, cutaneous torpors, disturbed sleep, furred tongue, nauseous taste, and anorexia, often gave way under this treatment within twenty-four hours; and a pulse hitherto jerking and irritable became calm and of the natural rhythm, while a soothing, pleasant sensation pervaded the system. No fever manifested itself in any of the cases; on the contrary, the person felt refreshed and buoyant. No other agent which I have ever employed has superseded carbolic acid as an apparent disinfectant of the malarious taint within the system; and this, after anxious thought on the subject for years, is to my mind the first glimmer of light that may lead to the discovery of means to act directly on the poison of fever."—*London Med. Record*, Aug. 15, 1879; *Dublin Journ. Med. Science*, September, 1879.

FARADIZATION IN THE TREATMENT OF PURPURA HEMORRHAGICA.—Mr. Shand, of Glasgow, reports a case of purpura hemorrhagica in which the use of electricity was productive of most pleasing results. Mineral and vegetable astringents, ergot, tonics, were tried, but the patient continued to sink rapidly. On the fifth day of treatment bleeding was taking place from vagina and bowels; she looked bloodless, collapsed, and apparently dying. She refused all medi-

cines. Electricity was thought of and applied; the interrupted current was used, running the sponges over the whole surface of the body. This was repeated every two hours, and at midnight no more motions had taken place, but gripping had set in. A piece of soap was now injected, and soon relieved her by producing two evacuations; the first consisted of blood, but the second was almost natural. The next day she was much improved, and the bleeding had almost entirely ceased. Tonics and astringents were again prescribed, and a speedy recovery followed. The electricity is supposed to act by exalting the tone of the nervous system, by facilitating coagulation, by toning the exhausted capillaries, and by encouraging the capillary circulation through acting as a general stimulant. Mr. Shand is in the habit of using a strong battery, with few interruptions, employing the upward and downward current indiscriminately, and does not pay much heed to Ziemssen's points of application.—*The Lancet*, July 19, 1879.

THERMOMETRY OF THE VISCERA.—At a recent meeting of the Berlin Physiological Society, Dr. H. Kroencker showed a number of globular maximum thermometers, and also some new cylinder-shaped instruments intended for introduction into the blood-current of living animals. Dogs could be made to swallow the globular thermometers without any trouble, while the cylindrical thermometers could be introduced into the femoral or internal jugular vein, or into the carotid artery without producing any disturbance. Those placed in the veins generally found their way into the peripheral branches of the pulmonary artery; occasionally, however, they were found in the azygos, the renal vein, etc., or remained in the right auricle—in a few cases in the right ventricle. Those placed in the central end of the carotid, and urged toward the aorta by injected blood, were driven to the remote arterial branches. Clots were occasionally found in the cardiac cavities from the presence of the thermometers, but not elsewhere. By means of these thermometers, the amount of heat developed during digestion, some notion of the temperature in different portions of the circulation, and the locality of the highest bodily heat were ascertained. The lowest blood-temperature of the inner portions of the body was found to be in the vena azygos (99.9° F.), the highest in the middle lobe of the right lung (105.9° F.) and in the empty intestinal canal (106° F.).—*Philadelphia Medical Times*, Aug. 30, 1879.

A NEW OPERATION FOR ENTROPION AND TRICHIASIS—Dr. Hotz, of Chicago, proposes for the relief of these affections a new operation, which from an experience of forty-six cases he believes to be far superior to any of the operations at present in use. The operation is based on his belief that incurvation of the tarsus does not play any important part in the development of the majority of the cases of entropion; that the edge of the tarsus does not generally change its relative position to the eyeball; and that the so-called rolling in of the lid is nothing more than an inversion of the external integument, which has been rolled down and in by spasmodic action of the orbicularis muscle. He was long ago struck by the fact that even in the worst cases of entropion, slight traction on the skin of the lid by means of a probe laid on the upper border of the tarsus, is sufficient to evert the inverted edge, and he has utilized this experience in his operation, which is carried out as follows: An assistant fixing the skin of the eyebrow against the supra-orbital margin, the free edge of the lid is seized with forceps about its middle and drawn downward

until the upper border of the tarsal cartilage is horizontal; an incision is then made along this border from a point 2 mm. above the inner to one 2 mm. above the outer canthus, and the orbicularis muscle is carefully divided, and its connections severed from the upper third of the cartilage. The lower flap of skin with the muscle attached is next everted, and a strip of muscle about 3 mm. in width is dissected off from canthus to canthus. This strip must be cleanly dissected off, and, at the same time, any shreds of muscle left adhering to the upper third of the tarsus should be removed. Four sutures are then applied; they are introduced 2 mm. from the border of the lower flap, carried through the aponeurosis in the upper third of the tarsus upward, to a little above the junction with the fascia tarso-orbitalis, and then out through the upper flap, care being taken that no muscular fibres are included within the loops. The sutures must be drawn tightly, so as to keep the skin in close contact with the cartilage. After the operation, cold-water dressing is applied for twenty-four hours, and then all dressing is left off, the eye being merely bathed frequently with tepid water to prevent the formation of crusts. The sutures should be removed on the third, or, if necessary, on the second day. The wound usually heals by first intention.

Dr. Hotz states that the immediate effects of the operation in all of the forty-six cases operated on, were complete removal of the entropion and great improvement in the appearance of the lids, and that these effects became more obvious with the lapse of time. The first case on which it was tried was one in which a previous operation by Arlt's method had failed to relieve the entropion, although it had shortened the lid so much that the patient was unable to close the eye. The effect was most satisfactory, and Dr. Hotz claims that it is precisely in these desperate cases that the operation achieves its most brilliant triumphs. As a result of the firm union obtained between the skin and the cartilage, both move as one piece; the movements of the lid are entirely free, and the eyelashes are as much everted when the eye is open as when it is closed. Even should contraction of the conjunctiva subsequently occur, and cause the edge of the cartilage to curve in, Dr. Hotz believes that the increased tension of the skin thereby produced would counteract any effect the incurvation could have on the direction of the eyelashes. The operation may, if necessary, be combined with additional measures, such as grooving of the cartilage, canthotomy, or incision along the free edge of the lid, and any redundant skin can, if desired, be removed at a later period. As a rule, it is better to operate on only one lid at a time for fear of too violent a reaction.—*Archives of Ophthalmology*, July, 1879.

AMPUTATION OF THE BREAST.—Dr. B. W. Richardson's particular fondness, says a correspondent of the *Louisville Medical News*, is removing diseased breasts, and he has a large practice in this line. He does the operation with serrated scissors, having frozen the parts with ether spray. He uses no water on the wound, wires it together, covers it with styptic colloid, bandages the arm down, to insure rest, puts his patient on her feet, never to bed, lets her ride and walk as much as she chooses, and eat what she pleases. In eight or ten days he removes the dressing, and generally finds the wound healed, and his success is almost invariable. Dr. R. holds the germ theory to be all nonsense, and carbolic acid he considers a bad-smelling sham.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, November 1, 1879.

THE ETHICS OF CONSULTATIONS.

THE danger of interference between physicians, while rendering professional services, is so great that the most stringent rules are laid down to prevent it. But that these are none too strict, every medical man who is brought much in contact with his professional brethren can attest. Particularly is this the fact with regard to the relations toward each other which should be maintained in consultations. Either the ethics of the profession are not sufficiently explicit upon this subject, or the greater number wilfully violate its provisions, for certain it is that there is need in many quarters for a rigid enforcement of discipline. Consultations are held at the instance of the patient or his friends, or at the suggestion of the regular medical attendant, or both. In either event the position of the consulting physician or surgeon is obviously a delicate one. Whether or not he is really better informed than the gentleman in charge of the case, the very fact of his being called at all removes, generally speaking, all doubts, at least in the mind of the patient, of his eminent fitness to give counsel and aid. The more critical the case, the more eagerly do the friends of the patient coax themselves into the belief of his superior qualifications. The attending physician, even if he knows that such a belief is without foundation, so far tacitly agrees with the convictions of the patient that he does not, as a matter of courtesy, strive to overthrow them. The consulting gentleman is thus admitted to the case with a hearty endorsement of all who are most concerned in the proper management of the case, and may, if he is not exceedingly careful in what he says or does, damage very much the estimation in which the family physician is deservedly held. The real purpose of extra advice in difficult cases is to aid the sufferer directly and the attending physician indirectly, the party consulted being only instrumental to that end. If this

fact were thoroughly understood and appreciated, a great deal of misunderstanding, and much bad feeling among different members of the profession would be prevented.

It is a matter for congratulation that the number of those who wilfully violate the trusts imposed upon them is small; but, on the other hand, the unintentional sinners are very numerous. Of the former, then, we need not speak; they are past reformation, and should be left to the full fruition of their dishonest, unmanly, and wicked practices. But to the latter class there is much to be said that may be productive of good.

One of the main causes of evil-doing on the part of this special class is a want of caution in their actions before the patient, based upon a false appreciation of their rights. They seem to forget that the absolute rights of a consulting party are far from being many. In fact, they are so few that it seems strange that they should not be known. As before remarked, the real office of the consulting medical man may be summed up under two heads: 1st, advice to the attendant calculated for the greatest good to the patient directly, and the cause of science indirectly; and 2d, a policy which shall tend to strengthen the confidence of the said patient or his friends in his medical adviser. Beyond this, under ordinary circumstances, he cannot go without endangering the good standing of the other practitioner. In order to fulfil his obligation properly, the only necessary communication with the patient should be during the consultation, and always in the presence of the regular adviser. This is the general rule, to which there is perhaps but one exception—and that is, when the party calling the consultation fails from one cause or another to meet his engagement. Then, after waiting a reasonable time, the consulting gentleman can examine the patient alone; but he should, under all such circumstances, give his opinion in writing only, and under seal. Those gentlemen who do the largest consultation business in our cities make it a rule, that is almost absolute, never to communicate directly with the patients or friends at the conclusion of the consultation, except it be necessary to endorse the physician in attendance. There is really no necessity for doing anything further. Every explanation that it is requisite to make is left to the regular adviser, and if the patients have the confidence in him which they should, they cannot doubt but that he will candidly state to them any new facts of importance which the consultation may have developed. On the other hand, if a consulting party thoughtlessly places himself in a position to be plied with questions, he is very sure, contrary to his best intentions, on some point of trivial importance, to be diametrically opposed to the party with whom he has been consulting. Any one must be more than ordinarily acute, who, giving positive answers to such interrogatories, will not differ

with another on some point. This being the case, it is obvious that the attendant is the most proper person to reconcile the trivial differences of opinion. Some consultants, in the absence of any agreement with the physician or patient to the contrary, are quite unwilling to understand that their services should cease with the first visit. We have known of some gentlemen who have so far forgotten common courtesy to the attendant, that they have not only continued to attend upon the case, but virtually taken such charge of it as to suggest on their own account the proper times of meeting. Such a course is not allowable, even if the patient's friends make a request to that effect, unless the physician fully agrees to the measure. If he cannot so agree he seriously compromises his self-respect by remaining in attendance any longer. But there are cases in which such a necessity may clearly exist, and which every right-minded person will not fail to appreciate; they are, in a word, such as require special surgical treatment, in the shape of operation. etc. The consulting surgeon, under such circumstances, becomes principal, inasmuch as he gives an entirely new direction to the case, and is responsible for the immediate effects of any particular operation. He is supposed to know best when the patient should be seen, and it is properly his duty and privilege to make his suggestions accordingly. But, when all the immediate danger is past, it is equally his duty to retire at once.

Again, there is sometimes a very free interpretation of the clause in the code of ethics regarding attendance upon such patients as have been previously under the care of another practitioner. Generally speaking, it is sufficient for the patient to state that he has concluded to change his physician, to make it warrantable for another medical man to give his services. This is a rule which has long ago been sanctioned by custom, and cannot be altered. The patient has a right to change his physician if he so pleases, and, having notified him to that effect (after having, of course, paid the bill), is under no more obligations to him. Any physician who would refuse to accept such a case would manifest a species of transcendental fastidiousness that could hardly be appreciated by the most upright member of the Medico-Historical Society. It is another thing, however, when a gentleman is called after having, during the same illness, attended the case in consultation. Under such circumstances he is bound, in honor, invariably to decline having any further thing to do with the case. As it is to be presumed that through the practitioner he became known to the family—that the same practitioner, perhaps, gave him his reputation—he must not in any manner supplant him. If the latter did not actually occur sometimes, it would appear almost like an insult to honorable men to refer to it as a possibility.

In regard to consultations with specialists, the same rules hold good. There does not generally seem to

be any necessity for wrong-doing on the side of the specialist, as such cases as require treatment at his hands are readily and generously delivered up to him. Viewing the subject then as a whole, there would seem to be no reasonable excuse for misunderstanding as to what is just in the premises. The code of ethics is very explicit in its interpretation of the rights of each, and if that is not at hand, every one can easily and safely apply the Golden Rule in its stead.

If always actuated by its teachings, there would never be room for misunderstandings in our professional intercourse. In view of the great importance of frequent consultations, this is an end for which we should hopefully and patiently pray.

LARDACEOUS DEGENERATION.

THE recent debates on this subject, at the London Pathological Society, have deservedly excited very considerable interest. There are not a great many questions in general pathology which appeal strongly to those not specially engaged in this work. Lardaceous degeneration, however, is so important and as yet incompletely understood a lesion, that a prospect of further light upon it may naturally excite a good deal of curiosity. It is, of all the degenerations, the most severe in its reaction upon the general system, and is second only to fatty degeneration in extent and frequency.

It cannot be claimed that the debates referred to satisfied more than the most moderate expectation, for there was only one important and definite outcome of the two nights' discussion. Much was done, however, to show the importance of the subject and the points that especially need further study.

Since the early idea that amyloid material was really an amyloid, that is, a hydrocarbon, was disproved by the analyses of Kekulé and C. Schmidt, the effort has been made to discover which of the albuminoid substances it resembled most. By finding this, its origin, it was thought, might perhaps be traced. Some progress has certainly been made in this direction, although one very essential point in the study does not seem to have been as yet accomplished. We refer to the complete and perfect isolation of the material itself. The characteristics of the substance are its peculiar reaction with iodine, its deficiency in potash salts, its insolubility in the gastric juice and in water, and its tendency to attack the blood-vessels. Now there are a number of albuminates which have more or less of these characters. Thus even the reaction with iodine occurs with acidified albumen and casein. In nearly every respect, however, it resembles most closely de-alkalinized fibrin. And this conclusion, now pretty well established, confirms a previous very plausible but not well-established hypothesis. For the fact that the degeneration, or infiltration, as some prefer to call it, first attacks the capillaries and arterioles, had led naturally to the be-

belief that the blood was the source of the morbid action; but the uniform failure to discover any traces of the amyloid substance in this fluid, as well as the peculiar manner in which it singled out only special organs for its attack, caused doubts about such an origin. These may now be quite confidently set aside. And on the whole, the most rational conclusion in regard to the nature of the amyloid material is, that it comes from the blood, and represents a defect in the nutritive changes in that fluid. It is a case, in fact, of incomplete or perverted metamorphosis. It may be asserted of this theory that it is not only a rational, but a fashionable one. The idea of asserts or perversions in the metamorphic process is now affording a happy explanation of a good many pathological phenomena.

With regard to less abstruse points in the subject debated, we find that a very positive as well as practical conclusion was reached in connection with the etiology of the disease. Dr. Dickinson, decidedly the best authority on the matter, claimed that the cause could be traced in every, or nearly every case, to syphilis or suppuration. This throws out a long list of occasional causes heretofore given, such as cancer, malarial poisoning, alcoholism, etc. Dr. Dickinson's assertion was well sustained, and pretty generally agreed to. If firmly established, it is a most important advance in our knowledge of the disease.

Although waxy degeneration may be cured in its earlier stages, it has always been thought entirely intractable when well advanced. It induces an atrophy and fatty degeneration of the tissues about it. When seated in the kidney, it is, in this country at least, always accompanied with a diffuse nephritis. Nevertheless, cases were related to the Society which serve to prove that even in the worst stages there may be retrogression and cure of the disease; and this not only in syphilitic, but suppurative cases. In one patient a liver, which reached nearly to the crest of the ilium, was reduced to its normal size; in another, a child in apparently the last stages of chronic albuminuria was restored to comparative health. No especially new remedies were used to secure these results. On theoretical grounds, liquor potassæ is recommended, but it is not efficacious unless combined with tonics and cod-liver oil, and there is room for the belief that the tonics and oil are the chief agents. Indeed, pathological investigations have not as yet much advanced the therapeutics of the disease.

PHYSICIANS' VACATIONS.—Much has recently been said about the necessity of vacations for physicians, but Dr. and Mrs. Ducat, of Highbury, England, have taken one. After putting themselves in training by a series of preliminary walks, they travelled on foot through Switzerland and along the Rhine for three weeks. They saw, it would appear, almost everything, and all for forty pounds. Their example is commended to the rest of the profession.

Reviews and Notices of Books.

MANUAL OF THE PRINCIPLES AND PRACTICE OF OPERATIVE SURGERY. By STEPHEN SMITH, A.M., M.D., Surgeon to Bellevue and St. Vincent Hospitals. New York: Houghton, Osgood & Co. 1879.

This is a rather closely printed, profusely illustrated royal duodecimo volume of 698 pages. It covers so large a field that the limits of our space forbid criticism in detail, and we shall therefore confine our notice to an examination of the general plan, in order to show the scope and character of the work, and to a minuter criticism of one or two subjects to show the manner in which the work has been done.

The central idea, as indicated in the preface, rests upon the legal obligations of a surgeon, and "it has therefore been a constant effort to give to the text the highest degree of authority, by embodying the teachings of recognized authorities on every subject, *so far as they conform to what is believed to be the present standard of surgical opinion and practice.*" (Italics our own.) If by this it is meant that the book is to be considered a medico-legal authority, and that compliance with its teachings, like the possession of a diploma in some countries, will throw the burden of proof upon the plaintiff in a malpractice suit, we cannot but think the design as illusory as the execution is defective. The error in the design is contained in the lines we have italicized, for only such teachings are accepted as coincide with the author's views, and only those teachers are considered as authorities whose utterances receive similar approval. The work, therefore, does not differ in this respect from any other similar treatise: it derives its authority solely from its author; and his indorsement, valuable as it is, is not sufficient to give any opinion the character of a final judicial decision.

The defects of execution are manifested in several ways, and while the allegation in some of them depends merely upon a difference in opinion between Dr. Smith and the reviewer, it will in others, we think, be accepted as correct by all. The citation of authorities is confined to the simple mention of the name of the individual without a single reference to the page, or even the book in which the opinion is to be found; the only guides even to the legal opinions and decisions are the names of the judges or of the parties to the suits. For legal purposes, therefore, they are almost valueless, because they offer no means of verification, and for practical purposes they are so incomplete that the practitioner must in many cases be unwilling to be guided by them, for he knows neither the considerations upon which they were based, the modifications they are subject to, nor even the date at which they were held. Moreover, some of them are evidently taken at second hand. These references are a prominent feature of the work; a count of those in the first fifty pages shows an average of more than three to a page, or over two thousand for the entire book. In spite of their number, we miss some that we might reasonably expect to see among them, and we find others that are simply trivial. For example: under amputations no reference is made to Cardin; in fact, no mention is made even of the long anterior flap, although that method is in daily use, and is sanctioned by such authorities as Lister, Holmes, and Erichsen; under amputation at the hip-joint no reference is made to Vernueil, although he is the inventor of a method that has proved successful, and

is the author of a recent and valuable paper upon the subject; under amputation at the knee, the only reference is to a maker of artificial limbs, an omission which, taken in connection with the fact that the only method described for amputating at this region is one introduced by Dr. Smith himself, throws a singular light upon his estimate of what is "the present standard of surgical opinion and practice." The general rules introducing the subject of excision of joints are fortified by only two references: one of them to Prof. Bigelow in support of the assertion that it is well to "preserve a useful hinge-joint at the elbow," the other to Hüter in support of a similar statement concerning the knee—the triteness of the one being equalled only by the impracticability of the other. No mention is here made of either von Langenbeck or Ollier, and yet one of the three divisions of the subject, that concerning the time at which excision should be performed, contains a recommendation of immediate excision, which is in direct opposition to the teaching of both these recognized authorities. Finally, in justification of our assertion that some of the references—we do not mean the statements—are simply trivial, we may refer to the one to Prof. Bigelow, just quoted, and to the following, taken almost at random from pages 15, 17, 50, and 325: "Foul air, filthy dressings, indigestible food, will thwart the best planned and executed operation."—*S. D. Gross*. "Excessive bleeding, due to defective measures for its prevention, is culpable negligence."—*F. Esmarch*. "Thermometry . . . is an important mechanical aid in diagnosis."—*A. L. Loomis*. "The best general rule for its application (that of a roller bandage) is as follows: It should be done quickly, without pain, with ease, and with elegance."—*Hippocrates*.

The scope of the book is far wider than one would expect, and the diversity of the subjects treated in it, and the manner of treating them, bring it into the class of surgical text-books, rather than into that of operative surgeries. Thus, to take the first two extreme examples that present themselves, we have, on pages 497 and 498, rupture of the kidney, the treatment to be rest, opium, and quinine; and on pages 283 and 284, inflammation within the cranium, with a full account of its pathology and symptoms, and no recommendation of operative interference beyond blistering and venesection. It seems to us that this fulness is only justifiable when the space for it is not obtained by slighting other parts, for the book is offered as a manual of operative surgery, and foreign matter should not be brought in to the exclusion or insufficient consideration of topics which are properly included in that title. The composition of the work is compact, and the type is not large, but it contains only 700 medium-sized pages in which space is further taken for 733 illustrations and 2,000 references in foot-notes. Nearly 50 of the first 80 pages are given to the following six subjects: The Obligation, Examination, Preparation, Emergencies, Repair, Cicatrization. These are followed by 30 pages on fractures, and it is not until the 111th page that the real subject-matter of the book is reached in general operations on the bones. At the 147th page a new digression begins, and 20 pages are given to dislocations and the diseases of joints. One-fourth of the book has been gone over, and the only operations described have been those for the resection of the different bones. In the remaining portion of the book the longest absences from the track that we have noted are 9 pages on injuries to the muscular system, and 11 pages on compensative appliances

(artificial limbs, etc.); but shorter lapses are frequent, and we think we are speaking within bounds in saying that more than one-third of the book is given up to subjects that do not strictly or properly belong in it, and the treatment of which is necessarily so scanty and superficial in most cases that the reader will be compelled to refer to other treatises for the needed information. This is only equivalent to saying that the book is not a satisfactory text-book upon general surgery; and although it may be claimed that it is not a general surgery in title, it certainly aims to be one in subject-matter.

Let us now see if the condition which we mentioned as offering, in our judgment, the only justification for this introduction of extraneous matter, is complied with. The number of pages allotted to each subject offers a ready, if somewhat rough, means of indicating the consideration each has received, and incidentally supports the assertion, made apparently with pride in the preface, that no "stereotyped" (that is, systematic) method has been followed. The following subjects have each been given one page: corns, boils, carbuncles, amputation of arm, forearm, thigh, at the elbow, and at the knee; hypodermic injection, $1\frac{1}{2}$; fistula in ano, thermometry, rhinoplasty, and amputation of the leg, 2 each; amputation at the hip, $2\frac{1}{2}$; the nails, 3; harelip, 3; acquired defects of the lips, 6; cæcum, 4; colon, 5 (without mention of inguinal colotomy); the rectum (exclusive of hemorrhoids and anus), 11; lungs, 6; larynx and nasal fossæ, each, 12; ligation of arteries, 36; operations on the bones, 36, and on the joints, 24; and, finally, the principles of amputation and of excision of joints are disposed of in $6\frac{1}{2}$ pages and half a page respectively. The last-named subject is treated under three heads—the indications, the time at which excision should be performed, and the method of operation. The only indications mentioned are gunshot wounds, compound dislocations, and progressive caries, to the exclusion of unreduced dislocations and ankylosis, although under ankylosis of the elbow, on page 642, he recommends excision, adding: "The steps of the operation are the same as for caries, except that a triangular piece of bone must be removed at the seat of the old articulation"—a statement which entirely ignores the radical differences in the method imposed by the immobility of the joint, and the recommendations of his own authorities as to the amount of bone that should be removed. Under the *method*, we have only a brief statement (12 lines), in general terms, of what the operator should aim to accomplish, but not a word as to the manner in which it is to be done—a treatment of the subject which might be proper in a general text-book, but which is inexcusable in an operative surgery.

To take another example: ligation of the common carotid is described clearly and with sufficient detail in $2\frac{1}{2}$ pages, while the more difficult and dangerous ligation of the external and internal carotids near their origin is described, with their anatomy, in less than half a page, and that of the external carotid above the digastric in 9 lines, of which 4 are given to its anatomy and 5 to the operation. In both cases the anatomy is descriptive rather than surgical, and lacks precision.

In the light of such descriptions and such treatment of the subjects, what are we to think of the statement in the preface that the lofty ideal there described had been constantly borne in mind, although manifestly unattainable?

To summarize our objections: Dr. Smith has at-

tempted to cover too much ground, and has therefore been compelled to treat most of his subjects incompletely. The numerous references are too indefinite to have much value; they abound where they are not needed, and are absent where most required. The treatment of the different subjects is uneven; many of them are treated exceedingly well, and the operative method given with sufficient detail, but in others the description is so brief that the practitioner would get little or no help from it. It seems as if the author had lost sight of the fact that he was writing for men whose knowledge and experience are less than his own, and had consequently omitted many directions which he would not need, but which they would find essential. The language is well chosen, and the composition simple and direct.

CLINICAL MEDICINE: A Systematic Treatise on the Diagnosis and Treatment of Diseases. Designed for the Use of Students and Practitioners of Medicine. By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine and of Clinical Medicine in the Bellevue Hospital Medical College, etc. Philadelphia: Henry C. Lea. 1879.

This book contains nearly 800 pages, and is the work of one of the oldest medical teachers and most accomplished medical writers in this country. Its author states that the plan of the work and the arrangement of diseases have been made with special reference to clinical medicine. In order to give the reader a fair idea regarding the scope of the volume, it must be stated that we find, first, an introduction in which are given modes of examining patients, methods of making clinical records and reports, and a general review of the subject of diagnosis as embracing general symptomatology, the use of the sphygmograph, the thermometer; also a study of the objects, ultimate and immediate, in treating cases of disease, and a chapter on the professional conduct of physicians toward their patients. Second, we notice that this book is divided into six sections. The first section is devoted to diseases of the respiratory system, and consists, first, of preliminary observations on symptomatology and physical signs, and, second, of remarks on the diagnosis and treatment of diseases of the respiratory system. The diseases which are considered in this section are: 1. The inflammatory diseases of the respiratory organs within the chest, including acute pleurisy, pneumonia, bronchitis and their varieties; 2. Chronic inflammatory diseases, including chronic pleurisy, empyema, and pleurisy with pneumothorax; 3. Structural diseases, including pulmonary emphysema and its varieties, pulmonary gangrene, carcinomatous and other tumors, etc.; 4. Functional diseases, such as hydrothorax, asthma, bronchial hemorrhage, etc.; and, 5. Diseases of the larynx. The author tells us that he has, "as far as practicable, arranged the diseases by grouping together those of which the diagnosis involves differentiation from each other." This fact explains the appearance, under the several headings in the sections, of diseases which properly belong elsewhere.

In this section we notice the author speaks of empyema as a disease that is "generally acute at the outset, but becomes chronic." In that respect he differs with some of our recognized authorities upon this subject. Acute miliary tuberculosis appears under the head of chronic inflammatory diseases of the respiratory organs of the chest, although the author regards it as a "constitutional affection," and one that may "not be inappropriately considered as an essential fever."

The subdivision, "Structural Diseases of the Respi-

atory Organs within the Chest," includes a class of affections which, in general, involve appreciable changes of structure without inflammation as an essential condition. At first, the heading was confusing; but, when coupled with the definition in the text, it is easy to understand the meaning of the author. The suggestion then is that the heading should receive an explanatory word. Another suggestion which your reviewer offers is, that the well-known views of the author regarding the essential nature of certain pulmonary affections would have warranted him in placing those diseases in a separate chapter, having an independent heading descriptive of the special views entertained. For example, diseases of the respiratory organs, essentially fevers.

In the second section, diseases of the circulatory system are considered. We notice, first, the preliminary observations on the symptomatology and physical signs of cardiac disease, and symptoms and signs referable to vessels; and, second, the diagnosis and treatment of diseases of the circulatory system. The diseases considered in this section are: I. Diseases of the blood; II. Inflammatory diseases of the heart; III. Structural diseases of the heart; IV. Functional disorders of the heart; and, V. Diseases of the vessels. This section has a classical appearance, and is a valuable digest from the pen of one of the masters in physical diagnosis.

The third section is devoted to diseases of the digestive system, and has the same general arrangement as that seen in the preceding sections. In the fourth section the author considers the diseases of the urinary system; and in the fifth section, the diseases of the nervous system. The fifth section occupies the largest space, and in it is included the consideration of mental affections. The sixth section embraces the consideration of fevers, continued, periodical, and eruptive, and other general diseases.

On page 684, under the heading "Prevention of Typhoid Fever," there is an intermingling of sentences relating to causation by means of drinking water and by breathing air containing effluvia from decomposing human fecal excrement, that is striking, and especially so in the light of the author's uniform clearness of expression.

We confess we are not a little disappointed regarding the general scope of this work. It does not possess the value we had expected to find when we compare it with the author's excellent treatise on "The Principles and Practice of Medicine." We cannot help believing that, had the author expended the same amount of labor in enlarging and perfecting his valuable treatise with which the medical world is already familiar, he would have rendered the medical profession a greater service and would have earned for himself a more enduring fame than that which will arise from his work on "Clinical Medicine."

The intrinsic value of the book has not been overlooked while offering the above criticism.

THE NATIONAL BOARD OF HEALTH.—Dr. Turner, Secretary of the Executive Committee, sent in his resignation as member of the Board. It was not accepted, but he has been given thirty days' leave of absence.

The *Bulletin*, which has been edited by Dr. Bailhache, and temporarily by Dr. Stephen Smith, has been, by resolution of the Executive Committee, placed under the direction and supervision of Drs. Billings and Turner.

Reports of Societies.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 16, 1879.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

THE Academy was called to order at 8.15 P.M. by the President. The minutes of the last two stated meetings were read by the Secretary, DR. H. T. HANKS.

The President introduced to the Academy Dr. Lee, of Oswego, and Dr. Bunn, of China, and invited them to take seats upon the platform.

LIBRARIAN'S REPORT.

The Librarian, DR. LAURENCE JOHNSON, reported that, since the last stated meeting in June, there had been donated to the library 900 bound volumes and over 4,000 unbound volumes and periodicals. Special mention was made of a complete set of bound volumes [110] of the *London Lancet*, from 1823 to 1876, presented by the President; 54 bound volumes of their own publications, by Messrs. D. Appleton & Co.; 368 bound and 502 unbound volumes, devised to the Academy by the late Dr. Henry S. Downs, a Resident Fellow; an autograph letter of Sir Astley Cooper, presented by Dr. Wm. Detmold; 64 bound volumes, presented by Dr. E. S. F. Arnold, of Newport, R. I.; 22 volumes of the *Natural History of the State of New York*, donated by Dr. J. G. Adams; the library of the New York Dermatological Society, presented by the society; 1261 *Medical Journals*, presented by Dr. C. W. Bernachi; 143 bound volumes, by Dr. J. H. Douglas; and an additional instalment of his library on cholera, by Dr. John C. Peters.

DR. S. S. PURPLE announced the presentation to the library, by Dr. Abram Du Bois, of 550 bound volumes, which were donated at a cost of \$1,318.28.

On resolution offered by Dr. Purple, the thanks of the Academy were tendered to Dr. Du Bois for his munificent donation.

Dr. Purple also announced the reception of a check for \$200 from Mrs. John Jacob Astor, to be expended in the purchase of books for the library.

On resolution offered by Dr. Purple, the Academy extended a vote of thanks to Mrs. Astor for her generous donation.

On motion made by DR. PIFFARD, a vote of thanks was extended to Messrs. D. Appleton & Co. for their donation to the library of the Academy.

On motion made by DR. JOHNSON, the thanks of the Academy were tendered to the Dermatological Society for its donation to the library of the Academy.

On motion made by DR. HUBBARD, the thanks of the Academy were extended to the President for his gift of the marble bust of Mr. T. Spencer Wells, the presidential chair and table, the Secretary's table, and the reading-table.

On motion made by DR. PURPLE, a vote of thanks was tendered to Mrs. Fanny C. Hartley, a daughter of one of the founders of the Academy, the late Dr. White, for a donation of \$200.

On motion made by DR. WM. T. WHITE, a special vote of thanks was tendered to the Building Committee, Drs. Purple, Hubbard, and Gouverneur M. Smith.

NON-RESIDENT MEMBER.

The Secretary read the resignation of Dr. John J. Mason as Resident Fellow, and, on motion made by Dr. Detmold, Dr. Mason was elected a Non-resident Fellow.

The next business in order was the lecture, which was given by DR. JOHN C. DALTON, on

CEREBRAL ANATOMY,

attention being directed especially to the anatomy of the corpus striatum.

The anatomy of the brain, said Dr. Dalton, is complicated in its details, but simple in its general structure. It consists of gray and white matter. The gray matter is arranged in two separate divisions, occupying two separate localities: 1. Exterior, convolutions; 2. Interior, cerebral ganglia, the corpus striatum, and the optic thalamus. The white matter is a continuation of the longitudinal columns of the spinal cord. The ascending fibres of white substance were then traced through the medulla, the pons varolii, crura cerebri, internal capsule, and to the fan-shaped expansion, the corona radiata. In the cerebro-spinal system, counting from without inward, there are three distinct deposits of gray matter: 1. The gray matter of the spinal cord; 2. The gray matter of the cerebral ganglia; and 3. The gray matter of the convolutions.

The doctrines now in vogue—even the recent views of Meynert and others, when divested of superfluous nomenclature—regarding the anatomy of the brain, were based upon the general view of three successive deposits of gray matter, connected with each other by three successive sets of white fibres. Of these three deposits of gray matter, the middle consists of the large cerebral ganglia, both of which occupy about the same level.

Dr. Dalton then referred to differences between the corpus striatum and the optic thalamus—the latter, on section, presenting a rather uniform gray tint, and the former showing white fibres arranged in bundles visible to the naked eye, and giving it a striated appearance. The corpus striatum was made up of two distinct parts: 1. Anteriorly, the intra-ventricular portion, or caudate nucleus; and 2. Posteriorly, the extra-ventricular portion, or lenticular nucleus. The optic thalamus was a single ganglion by itself. Of late it had become quite customary to restrict the term, corpus striatum, to its intra-ventricular portion.

He then alluded to the situation of these masses of gray matter with relation to the internal capsule and the crura cerebri, and passed to the consideration of the internal capsule. It could not be seen that the internal capsule was composed throughout of fibres which run continuously from the medulla oblongata below to the convolutions above, but, on the contrary, there was a strong conviction that they were not the same fibres, and that in the passage from below upward there was an interchange of fibres, in the cerebral ganglia, not visible to the naked eye. In a physiological point of view there was no doubt that it was the channel of conduction between the hemispheres and the spinal cord.

Dr. Dalton then passed to the consideration of certain general and specific differences between the human brain and the brains of animals. The general difference consisted in the greater development of cortical substance. The specific differences were two: first, the fissure of Sylvius was double in the human subject, consisting, 1, of a posterior branch, which was simply an elongation of the Sylvian fissure, as

seen in the brain of the fox; and 2, an anterior branch; and between the two there was a triangular mass which was known as the *operculum*, and below them a group of convolutions known as the island of Reil. He then directed attention to the formation of the fissure of Rolando, which was simply a dividing line between the descending and ascending portion of a curve the convolutions made in addition to the double curve formed on the convexity of the hemisphere; to the cuneus, the precuneus, and the paracentral lobule; to the gyrus fornicatus; and then spoke of the special anatomy of the corpus striatum, which was usually described as a gray mass having an enlarged club-shaped extremity, directed forward and occupying the anterior horn of the lateral ventricle, and a cylindrical tail-like prolongation directed backward, and running along the outer edge of the lateral ventricle and terminating somewhere about the posterior end of the optic thalamus. In reality it was much more extensive than that. In fact, the extent of the corpus striatum was almost that of a complete ring encircling the crus cerebri and internal capsule, exactly as did the gyrus fornicatus. That arrangement could sometimes be seen simply by opening the lateral ventricle throughout its entire extent. It had enlargements in its course, and was more or less interrupted by oblique fibres, which came from the *tænia semicircularis*.

The anterior extremity of the corpus was connected with the gray matter of the convolutions at the base of the brain, just in front of the Sylvian fissure; and in a similar way the end of its curved portion was connected with the gray matter at the inferior extremity of the posterior horn of the lateral ventricle, with the amygdala just underneath the lenticular nucleus. In the smaller portion of the corpus striatum the striations were lost. The corpora striata were masses, which correspond in structure exactly with the remainder of the hemispheres.

In the discussion that followed, Dr. E. C. SEGURN directed attention to two points: 1. The great importance of clearly separating the nucleus caudatus from the nucleus lenticularis. They were almost completely separated anatomically, and the functions of the two parts were distinct. The nucleus caudatus had a more intimate connection with the motor tract than had the nucleus lenticularis.

2. The importance of understanding the true relations of the internal capsule. If any fact had been demonstrated by the help of pathological anatomy, it was that there was a continuous connection, by means of the white matter, between the cortex of the brain and the spinal cord. It was interesting to notice the growth of opinion relative to the physiological importance of the internal capsule, the nucleus caudatus, and the nucleus lenticularis. There were competent observers who doubted whether hemorrhage into the lenticular nucleus was a cause of hemiplegia. Charcot was of the opinion that the hemiplegia was produced by the pressure exerted upon the internal capsule. If the lesion destroyed the anterior portion of the internal capsule, motor disturbances followed; if the lesion was in the posterior portion, sometimes distinct motor symptoms were developed, but most prominently sensory disturbances upon the opposite side.

Dr. E. G. JANEWAY referred to a case which threw doubt upon the belief that destruction of the posterior part of the internal capsule always produced hemianesthesia. In a case of hemiplegia the leg almost entirely recovered, the arm remained a trifle stiff, but possessed considerable power, and there was

no anesthesia. The patient died a year and a half afterward, and it was found that the lesion involved the entire posterior two-fifths of the caudate nucleus, all the internal capsule between it and the lenticular nucleus, besides producing well-marked atrophy of the lenticular nucleus and anterior part of the optic thalamus. With reference to effects produced by lesion in the lenticular nucleus, he referred to a case in which a tumor was limited to that region, was not capable of producing much pressure on surrounding parts, and yet the symptom was simply aphasia, with a certain kind of dizziness having no special significance. He had also seen a case in which the lenticular nucleus was the site of an old cyst, which produced persistent aphasia. How explain the aphasia?

Dr. Wm. H. WELCH said that the valuable contribution of Dr. Dalton to the anatomy of the corpus striatum proved that there was still room for work in the topographical anatomy of the brain. The statement of Dr. Dalton, concerning the termination of fibres of the internal capsule in the basal ganglia, needed modification, since the researches of Flechsig had shown that the fibres which convey voluntary motor impulses from the central convolutions passed through the posterior third of the internal capsule, without terminating in the caudate or the lenticular nucleus. This discovery was in opposition to Meynert's theory of the three projection systems. Dr. Janeway's case of absence of anesthesia with a lesion of the posterior part of the internal capsule, was rather in accord with Flechsig's views than with those of Charcot, who placed the motor fibres in the anterior two-thirds of the internal capsule.

Notwithstanding Meynert's brilliant investigations, the purely anatomical methods, while they taught us the topography of the brain, had given us very little certain information concerning its inner architecture—that is, the course pursued by nerve-fibres and the connections between the different nerve-centres. For a knowledge of these most important relations we were to look also, in the future, to embryology, comparative anatomy, pathology, and experimental physiology. Flechsig's embryological researches and the experiments of Gudden on young rabbits were referred to. Comparative anatomy might be expected to give important information, after the homologies between the different parts of the brain of man and those of the lower animals had been more clearly determined than was yet the case. But caution was requisite as regards applying directly to man the observations made on the nervous system of the lower animals, since it had been shown that the pyramidal-fibres, for instance, occupy very different parts of the spinal cord in different animals. As a basis for the study of the localization and of the connections of nerve-centres and of nerve-fibres, an accurate topographical anatomy of the brain was indispensable.

Dr. W. A. HAMMOND, on invitation, remarked that it was held by neurologists in general that lesion in the optic thalamus was followed by temporary paralysis upon the opposite side and hemianesthesia; that a lesion confined to the intra-ventricular nucleus gave rise to transient hemiplegia upon the opposite side, with derangement of sensibility; that a lesion involving the extra-ventricular nucleus also produced transient hemiplegia upon the opposite side; that a lesion involving the anterior portion of the internal capsule produced permanent hemiplegia upon the opposite side, much more so than lesion involving either the corpus striatum or optic thalamus; that a lesion involving the posterior two-thirds of the

internal capsule produced permanent paralysis, hemianæsthesia, and permanent contraction of the muscles. He thought that when contractions of the muscles came on later they were not cerebral in origin, but depended upon secondary degeneration of the spinal cord.

DR. DALTON replied to Dr. Welch, who thought that we should look for the most permanent advancement in our knowledge of the brain in pathological observation and physiological experiment, because so little real information had been obtained by purely anatomical investigations, and did so with the greatest respect for his opinion, by entering a protest against this view, for the reason that too much had already been done in that direction. For example, a section is made directly through certain nerve-fibres and certain effects are produced upon distant parts, and immediately we deduce anatomical facts from physiological experiment—a method of reasoning which he believed was entirely wrong. The same was true with regard to pathology. For example, a tumor in a certain portion of the brain is associated with symptoms produced in a certain part of the body, but it was impossible to say that nerve-fibres extended from the first place to the second. He thought one of the faults that had been committed was conducting purely anatomical investigations of the brain by means of physiological experiments and pathological observations. Both had their distinct values.

DR. E. C. SPITZKA, on invitation, spoke of the development of the corpus striatum in the lower animals, and also in man, and said that he had found the portion most posterior, to be composed more of neuroglia and atrophic elements, than of real ganglion tissue. With regard to Dr. Dalton's interpretation of the amygdala, he thought it would bear further investigation. He also thought that the results obtained by Flechsig, referred to by Dr. Welch, had been overrated, for F. had so confounded anatomical parts that his opinion could not be regarded as one having very great value. He then spoke regarding the striated appearance of the corpus striatum and the arrangement of the convolutions.

DR. WELCH remarked that he placed physiological experiments as the least valuable, of those mentioned, as a means of research. He thought, however, that experimental physiology and pathology had been of no slight service, inasmuch as they had taught us the location of psycho-motor and psycho-sensory centres, in the cerebral cortex, and the course of certain groups of important nerve-fibres in the brain and the spinal cord.

The Academy then adjourned.

Correspondence.

"THE DISCOVERER OF ANÆSTHESIA."

THE CLAIMS MADE FOR DR. LONG CRITICISED.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—On the occasion of the presentation in connection with the subject embraced in the above title, of the double portrait of Drs. Long and Sims to the Legislature of the State of Georgia, an event described in a late issue of the RECORD, a distinguished speaker* is quoted as using the following words: "It so happens that we are indebted mainly to Dr. Marion Sims . . . for the final and almost unquestioned recognition of Dr. Long as the real discoverer of anæsthesia."

A statement, grave and unjust as this is, and emanating from an authority* as high as apparently misinformed, merits a notice, not yet, now for two years, accorded from any source to the senator's informant. But filial if not indeed abstract duty now demands a word. Under these circumstances, Mr. Editor, will you kindly allow me, uninviting and ungracious as the task of controversy may be, and reluctant as I am to see its inherited shadow even, falling in my direction, a brief space for a passing memorandum.

In 1849, three years after the practice of anæsthesia by sulphuric ether began and became universal as a result of the Boston revelation of 1846, Dr. Long, above referred to, for the first time in print, or writing, or otherwise publicly, made the tardy statement † that he had experimented with ether twice in 1842 and three times subsequently in as many successive years. Curiously enough, in this communication Dr. Long records not alone that he "used ether"—a fact which no one would wish to deny—but in the same moment, also, that he did not use it in a manner or to an extent satisfactory in its results either to himself or others. This, indeed, might be inferred from the facts that in the course of the four years over which his experiments extended, no one else used ether, and that neither then nor later was ether used because he had used it, or from any knowledge of his five experiments. But it is more convincing to find the confession that, as we shall see later, his experiments were total failures, and finally abandoned, recorded in his own language. Very naturally, Dr. Long's statement passed unnoticed at the time it was made, both because it had no bearing upon the events of 1846, because the medical world contemporaneous with the period of his alleged experiments, 1842-46, had no knowledge of the existence of any practice of anæsthesia, and because, as we have said, his experiments covered no more than the technical claim of a "use" of ether—confessedly unsuccessful. It is more than probable, indeed, that this after-clap statement would never have seen light but for the world-wide fame which greeted the discovery of 1846. Dr. Long was only one of dozens who were stimulated at that time and later to relate past experiences and experiments with anæsthetic agents, any one of whose narrations could to-day be made to serve the same purpose that Dr. Long's account is now being made to serve.

Almost nothing further was heard of Dr. Long's tardily-recited experiments until 1877, when they were resurrected by Dr. J. Marion Sims and made the peg on which to hang a claim to the whole discovery, and designate their author "discoverer of anæsthesia" ‡. This claim made for Dr. Long in 1877, unjust, sophistical, and Quixotic as it was, extended to limits unauthorized by anything that Dr. Long ever wrote, and garnished by incidents and statements demonstrably false, has remained unanswered up to this moment. But your account of the proceedings in the Georgia Legislature indicate that the motives for silence have been mistaken, that silence has been misconstrued into consent, and that squatter rights have grown by default of contradiction into a sense of quasi-proprietorship. It is indeed true that Dr. Long's "claims" have not been questioned. The scientific world, which has long since regarded this controversy as settled, is not usually roused into contradiction or questioning by the adventurous title of "discovery" applied to a short half-dozen of crude, unnovel, isolated, unannounced,

* Senator Gordon.

† Southern Medical and Surgical Journal, Dec., 1849.

‡ Virginia Medical Monthly, May, 1877.

* United States Senator Gordon.

fruitless, and abandoned experiments attached as an after-thought to a great discovery. And, because unquestioned, it by no means follows that any "final recognition" of them exists, unless, indeed, it is the proceedings attending the presentation of the dual portrait alluded to. Beyond this it is not known that the claims set up for Dr. Long have been in the slightest degree recognized. And it is, perhaps, a little hasty to assume that the Legislature of Georgia can make a recognition final upon the testimony of one witness whose evidence has not been questioned even. Such judgments are usually rendered after hearing both sides of a case, and that not from the mouth of a single advocate. Legislative snap-judgments of this nature can scarcely do less than reflect upon the integrity of their authors.

The limits of a memorandum forbid any further allusion to the presumptive and historical evidence against the claims made for Dr. Long. We pass on to evidence of fact, first noting a certain ambiguity in the terms "discovery of anæsthesia," favorable to the after-crop of "discoverers" which usually follow in the wake of a great discovery. In the word anæsthesia exists two meanings: the abstract fact or law of insensibility to pain, however induced or occurring, *i. e.*, the science, and the method, process, and practice of inducing this state for surgical operations, *i. e.*, the art. Discoverers find out something which has always existed, but which has not been known. Galvani discovered galvanism, but galvanism had always existed. Inventors combine known scientific or other principles so as to produce something utterly new, *i. e.*, a new machine or process. Now, anæsthesia, the abstract principle, is as old as human observation. It was not given to Dr. Long or any known man to "discover anæsthesia" in this sense. But the practice and the process of anæsthesia was new—the result of a combination of many known scientific factors. It was, therefore, an invention—the invention of anæsthetic inhalation for surgical purposes.

Did Dr. Long make this invention? Before answering this question we will formulate, for the sake of brevity, several propositions bearing upon the origin of the invention. These are:

1. That the scientific fact of a state of insensibility to pain had always been known.
2. That the quality inherent in certain medicaments, whether gases or liquids, and other agents to produce this state, whether by inhalation or potion, or other effect, had equally always been known; it was known, for instance, that the vapor of sulphuric ether caused insensibility to pain, though its use was stated to be attended with danger to life.
3. That what was unknown was the application to the surgical needs of humanity, of the process of inducing anæsthesia, an application demanding demonstration, not only of its possibility (a fact which was known), but also of its possibility in a safe, certain, efficacious, in short, available manner. Such a demonstration and application required the use of any known medicament to an extent (if ether, of stupor), and in a manner up to that time unknown. It would be essential also to announce this invention.
4. That many individuals had attempted to make this demonstration and application, *i. e.*, invent the anæsthetic process.
5. That demonstration and application to human affairs constitute the sole basis to a tenable claim to the invention or "discovery of anæsthesia," for one reason among others, that all else was known to modern times, *i. e.*, the conception or abstract idea

of anæsthesia, and the intention and attempt to produce it for surgical operations.

6. That this invention was not made until 1846, (a) because all the world agrees that its practice and knowledge of the anæsthetic process began then; and (b) because up to that moment both the word and the practice were unknown to surgery, or to surgical or other literature.

7. That Dr. Long did not make this invention in 1842, or later, *i. e.*, did not "discover anæsthesia" then, or ever.

It is with this latter proposition that we shall at present deal.

As we have seen, the anæsthesia of which we speak, is an invention, a process, an art. And we may confine ourselves to the simple question, who invented it? (We cannot speak of a discovery, when nothing to discover existed.)

Now Dr. Long stated in 1849, that he was "the first to use ether as an anæsthetic in a surgical operation," and this in 1842. Dr. Sims, in 1877, claims for Dr. Long, that "he was the first man to intentionally produce anæsthesia for surgical operations, and that this was done with sulphuric ether in 1842."

But, in doing what Dr. Sims claims for him, Dr. Long did not advance one step beyond the works of many before him. And we allude here to modern times only.

M. Dauriol, in 1832, specifies five cases in which he "succeeded in performing painless operations."

Hickman, of London, in 1828, details a method of "suspending sensibility by the methodical introduction of certain gases into the lungs," during which "the most delicate and most dangerous operations are performed without producing pain in the individuals submitted to them."

Did Dr. Long do more than Hickman, or Hickman more than his predecessors, *i. e.*, fail to establish their process?

Collier, of Louisiana, performed five painless operations upon patients rendered insensible by alcohol. And Esdaille, Haller, Deneux, Blandin, and many others report painless operations.

If the statements just made are true, Dr. Long was not "the first man to intentionally produce anæsthesia for surgical operations." Dauriol, Hickman, Collier, Esdaille, and many besides them preceded him. These men are discoverers just as much as Dr. Long is. This, indeed, disposes of Dr. Sims's claim for him.

But Dr. Long himself says that he was "the first to use ether as an anæsthetic in a surgical operation." Now, the agent employed is perfectly immaterial, whether one vapor or another. The claim of "use" of this or that agent is an insullicient one. The question, of course, is to what extent, and in what manner was ether used. Was it so used as to establish the invention of anæsthesia? Aërial navigation is to-day a chimera. But the man who makes travelling through the air as practicable as Fulton made steamboat travel, or as Morse made telegraphy, or as Morton made anæsthesia, will certainly never have any peace from the clamor of the men who had previously "used" balloons.

But at this point we may ask, wherein did Dr. Long fail? Simply in this, because he fulfilled none of the requisites of an invention. Science does not accept crude, unestablished, unaccepted experimentation as an invention. It requires a perfect demonstration. The invention must leave the inventor's hand in such a form, that others are able to repeat, accept, and practise it. Upon this point, scientific

precedent as well as the laws of the land agree. As is clearly stated by Chief-Justice Story, than whom no higher authority upon this point exists, the invention must be in such form that others may be able "to produce precisely the result described, by using the means specified, without any addition to or subtraction from them."

Dr. Long did not do this. No one repeated his experiments—not a physician or surgeon used ether because he used it, and medicine did not learn from him that anæsthetic inhalation for surgical operations was practicable.

Thus far we have written without "questioning" the verity of Dr. Long's five cases of anæsthesia. Granting all that is claimed for him, we wished to show that even then he could in no wise be considered as the inventor of anæsthesia. We will now prove in his own words that he never produced the anæsthesia, which we have for the moment admitted. In doing this his claim falls doubly flat,

"And error . . . dies among his worshippers."

In his communication, already referred to, made in 1849, Dr. Long says: "*The result of my second experiment in etherization was such as led me to believe that the anæsthetic state was of such short duration that ether would only be applicable in cases in which its effects could be kept up by constant inhalation during the time of the performance of the operation. Under this impression, up to January, 1847, I had not used ether in but one case in extracting teeth, and thus deprived myself of experimenting in the only class of cases which are of frequent occurrence in a country practice.*"

This quotation shows exactly what Dr. Long's "anæsthesia" was. It comprises his whole idea of anæsthesia—from his second experiment in 1842 "up to January, 1847," three months after Morton's anæsthesia of October, 1846. What then does he mean by the term—was it the anæsthesia of to-day, or has he applied the term improperly? Dr. Long obtained certain "effects" which were of "short duration," "of such short duration" that ether would only be applicable in cases in which these effects could be kept up by constant inhalation."

What class of cases can Dr. Long refer to as those in which ether would *only* be applicable? He evidently does not think that there are many cases in which it would be applicable, for, under this impression, he had used it in but one case in extracting teeth during a period of five years. And how reconcile this with the familiar fact, that the anæsthetic state of to-day, and dating from 1846, can be kept up in *all* cases and as long as the surgeon pleases? If this state can be kept up now it could have been kept up in 1842, if Dr. Long had known that it could. And if he had known this he would have resorted to *constant inhalation* and have produced an anæsthetic state of long duration. But that he did not know this is more than a reasonable inference. It is established by his own admission. For, "under this impression, up to January, 1847," he had "deprived himself of experimenting in the only class of cases which are of frequent occurrence in a country practice." But why deprive himself of prosecuting his experiments in the simplest and most available cases? The answer to this question is inevitable; it is simply that "anæsthesia," as he understood it, was inapplicable because it was impracticable. It was not "anæsthesia" in any proper or recognized sense of the term.

This is an admission on Dr. Long's part in the clearest terms that his five experiments were failures; that they did not offer sufficient encouragement to

justify him in continuing them in the simplest of minor operations; that, in short, he abandoned "up to January, 1847," all that is now claimed that he "discovered." The reasons why Dr. Long's anæsthesia was impracticable and abandoned are to be found throughout his communication. One curious conjecture arises frequently; this is, that Dr. Long did not give the ether by his own hand, but left it to the patient, who, in the first two experiments at least, had long been in the habit of "inhaling ether for its exhilarating effects." Venable, the subject of the first two experiments, and from whose neck in each a vein was removed, deposes on oath, "*I commenced inhaling the ether before the operation was commenced, and continued it until the operation was over.*" There is a choice of horns in this dilemma. If Venable was etherized as patients are etherized to-day, he could not swear that "he continued it until the operation was over." If he did know what took place, then he was not etherized as patients are etherized to-day. Of the second experiment, Venable swears, "*In this operation I stopped inhaling the ether before the operation was finished,*" giving this as a reason for feeling a "little pain" when "the last cut was made." This is the experiment, be it noticed, which taught Dr. Long that the "anæsthetic state was of such short duration," etc. The situation is perfectly clear. Venable was administering the ether to himself; the state was short because his hands would naturally drop from his face before either unconsciousness or anæsthesia supervened. In his whole article Dr. Long does not once say that he himself held the towel or sponge. This may be inadvertence. If a true statement of the case, it shows that the "effects" alluded to were simply those of intoxication, or, as Dr. Long everywhere says, "exhilaration;" it shows why Dr. Long's "anæsthesia" was imperfect, impracticable, and abandoned. Dr. Long himself says of the first operation: "*The patient continued to inhale the ether during the time of the operation.*" (Inhale is used throughout the article in the sense of the act of giving the ether.) And of the second operation: "*In this operation the inhalation of ether ceased before the first incision was made; since that time I have invariably desired patients, when practicable, to continue its inhalation during the time of the operation.*" These words are meaningless, unless it is accepted that the patient gave the ether to himself. Grant that the patient was the administrator, and we must grant that the etherization was incomplete; and that the anæsthesia in this second operation was incomplete, both Venable and Dr. Long admit. Venable says he felt a "little pain" when the last incision was made; Dr. Long says "he exhibited signs of slight suffering." We dwell perhaps a little minutely upon this second operation, because it is the one which forms the basis of Dr. Long's declaration of faith—the one whose results taught him that the process which he afterwards dignified with the term anæsthesia was impracticable. And no later experiment taught him more than this. We have the curious exhibition of a man in the same breath with which he is attempting to establish a claim, declaring with absolute clearness that his efforts were a failure.

But the evidence is cumulative that Dr. Long was experimenting merely, and had no notion of the anæsthesia of to-day. He says:

"While continuously" (one case annually, be it noted, from 1842 to 1847) "experimenting with ether, with a view of *fully testing** its anæsthetic powers and its applicability to severe as well as minor

*Italics ours.

surgical operations ("I had no opportunity of experimenting with it in a capital operation"),* others more favorably situated, engaged in similar experiments, and consequently the publication of etherization did not bide my time." Well, the world is sorry; but if Dr. Long had not "fully tested" the anæsthetic powers of ether, his time evidently had not come. Another "fully tested" the anæsthetic powers of ether in 1846. *Hinc illæ lachrymæ.*

Dr. Long explains in another place why he was uncertain and doubtful of his results—why they needed more testing. He writes:

"The question will, no doubt, occur, why did I not publish the results of my experiments in etherization soon after they were made? I was anxious, before making any publication, to try etherization in a sufficient number of cases to *fully satisfy my mind that anesthesia was produced by the ether*" (italics ours), "and was not the effect of the imagination or owing to any peculiar insusceptibility to pain in the persons experimented on. At the time I was experimenting with ether, there were persons 'high in authority' who were advocates of mesmerism," etc. These terms anesthesia and etherization glide glibly from Dr. Long's pen, but it must be remembered that they are the words—the plumes—appropriated from the man who did not "bide his time," and we begin to see from Dr. Long's confessions what bare limbs he is decking out in the borrowed finery of 1846; not till then, evidently, was his mind fully satisfied that anesthesia was produced by the ether.

Great stress has been laid upon the argument that Dr. Long should not suffer from his failure to publish his experiments. We may waive argument upon this point, and submit as a substitute the remark that Dr. Long had nothing worth publishing. For supposing that he had printed in a scientific journal the results of five experiments not yet fully tested and about which he was not yet fully satisfied as to whether they were due to imagination, idiosyncrasy of the patient, mesmerism, or ether, can it be for one minute believed that the world would have hailed him as the "discoverer of anesthesia?" And is not such a claim, set up for him, in mild terms at least presumptuous? And further, according to Dr. Long's positive avowal, he contributed no information whatsoever to the world; his existence even was unknown to the actors in the events of 1846, the date of the beginning of the universal practice of anesthesia. Truly the title of "a world's benefactor," so freely bestowed in the legislative proceedings alluded to, is an extravagant term to apply to a man who confessedly gave the world nothing. If Dr. Long had made an invention or discovery he owed it to the world to tell of it. If he had not, he did well to keep silent. With a discovery of such incalculable worth in his hand it is a question as between Dr. Long and the world whether his conduct was not more disgraceful than pardonable. All the unrelieved agony of those four years lies at his door, that is to say, if he was a "discoverer;" but if he was waiting to experiment, to test, to remove his doubts, then he was neither inventor nor discoverer, and the world can excuse him. We think that his conception of anesthesia, as he himself has expressed it in the quotations we have given, quite justifies his silence, and equally exonerates him before the world of being either inventor or discoverer.

Dr. Long, then, to sum up, left the anæsthetic process where others had left it, and where he found it—a thing possible and to be desired, conceived of and

attempted, but not demonstrated to his own or any follower's satisfaction, and not applied to human affairs or established. And more than this, in failing to publish the results of his experiments, and in thus avoiding contemporaneous (1842-1846) scientific and popular criticism, he vitiates the merit of any subsequent claim made and interpreted in the light of the established facts of others who dared such an ordeal.

And here we leave the subject, conscious that we have endeavored to do Dr. Long and his promoter the fullest justice, and in taking leave of them we ask an impartial and candid profession, if it does not appear that his friends, in giving Dr. Long the comprehensive title of "discoverer of anesthesia," are claiming far too much for him?

WILLIAM J. MORTON, M.D.,

53 EAST THIRTY-THIRD ST., Saturday, Oct. 18, 1879.

Obituaries.

GEORGE W. CALLENDER, F.R.S.,

LONDON, ENG.

THIS eminent English surgeon died on board the steamship Gallia, which sailed from this port for Liverpool Wednesday, October 15, 1879. During his visit to this country in 1878 we were favored with the opportunity to give to our readers some of his practical instructions in the details of surgical dressings. His simple yet effective manner of protecting his patients from unnecessary pain, and his unostentatious style in presenting his views upon any subject won for him a multitude of admirers in the medical profession. He determined to pay the United States another visit, and accordingly, on the 26th of August, 1879, he sailed from Liverpool on the steamship Gallia, and arrived early in September. Almost immediately after his arrival he became the guest of his old friend, Mr. George W. Childs, the editor of *The Public Ledger*, at his country seat at Long Branch, where he remained for some time. He then spent considerable time in visiting friends in various localities, and, when taken sick, he was at the house of Mr. Henry C. Lea, of Philadelphia. He at once placed himself under the medical care of Dr. Da Costa and Dr. Levis, and was seen by other Philadelphia physicians. Previous to this sickness he regarded himself as a healthy man, and had not the least suspicion with reference to the disease from which he was suffering. Dr. Da Costa suggested that his urine be examined, and Mr. Callender made the examination himself, when he found it loaded with albumen. His feet were then œdematous, and his pulse was feeble. His urine, on microscopical examination, was found to contain large and small hyaline and granular casts, had a specific gravity of 1014, besides a large quantity of albumen. Having a desire to reach his home, his physicians consented that he should attempt the journey, and accordingly he was brought to New York in a special train and carefully transferred to his state-room in the Gallia, which sailed as above mentioned, and a cable dispatch to Mr. Childs announced that he died on the Monday following the day of his departure.

His affection was Bright's disease of the kidney, and he was about fifty years of age when it terminated fatally.

Mr. Callender served as Demonstrator of Anatomy in St. Bartholomew's Hospital twelve years; was then

* Quotation from another place inserted here.

made Professor of Anatomy, and afterwards Surgeon to the same institution, to succeed Sir James Paget.

He was Professor of Anatomy in the University of London, and in February, 1879, was appointed Professor of Surgery in the same institution. He was also Examiner in Anatomy in the University of Cambridge.

He was made a member of the Royal College of Surgeons July 16, 1852, and a Fellow, November 15, 1855. He was also a Fellow of the Royal Medical and Chirurgical Society, and Consulting Surgeon to the Western General Dispensary.

His writings consist chiefly in papers published in the Proceedings of the Royal Society, the Philosophical Society, the Medical and Chirurgical Transactions, the St. Bartholomew Hospital Reports, and in the *Journal of Anatomy and Physiology* and *Medical Journal*. Some of his papers are very elaborate, and possess great scientific value. Among them is a very interesting paper on "The Formation of the Sub-axial Arches in Man," read March 16, 1871; a paper on "The Formation and Early Growth of the Bones of the Human Face." Both of the above papers were communicated by Sir James Paget to the Royal Society, and the latter was read in June, 1868.

In 1863 he read an able paper on "The Anatomy of the Parts contained in Femoral Rupture." He was then Assistant Surgeon and Demonstrator of Anatomy in the St. Bartholomew's Hospital. He also had done some original work with reference to the development of the thyroid gland and the human brain.

By his modesty, his scientific attainments, his gentle disposition, and his social abilities, he endeared himself in the memory of the many Americans with whom he became acquainted during his visits to this country.

He fell in the prime of his manhood, and in the midst of his usefulness, and will be mourned by the whole medical profession.

EDWARD L. McWITHEY, M.D.

ONE of the younger graduates of the College of Physicians and Surgeons in this city, Dr. Edward L. McWithey, died suddenly October 24, 1879, of Bright's disease, at his residence, No. 326 West Thirty-fourth Street, at the age of twenty-seven years. His professional career was commenced in Greenville, Jersey City, and he pursued his studies with such success that he rapidly attained an excellent practice. His disease resulted from an attack of diphtheria contracted in 1877.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 19 to October 25, 1879.

WOLVERTON, W. D., Major and Surgeon. Assigned to duty at Fort A. Lincoln, D. T. S. O. 115, Dept. of Dakota, Oct. 18, 1879.

CALDWELL, D. G., Capt. and Asst. Surgeon. Upon withdrawal of troops from Ft. Independence, to report to Comd'g Officer, Ft. Warren, Mass., for duty as Post Surgeon. S. O. 165, Dept. of the East, Oct. 20, 1879.

BARTHOLF, J. H., Capt. and Asst. Surg. His temporary detail at San Diego Barracks, Cal., to terminate on 31st inst., and to return to Alcatraz Island, Cal., and resumé his duties as Post Surgeon. S. O. 130, Div. of the Pacific and Dept. of Cal., Oct. 15, 1879.

KILBOURNE, H. S., 1st Lieut. and Asst. Surgeon.

Assigned to duty as Post Surgeon at Fort Porter, N. Y. S. O. 189, Dept. of the East, Oct. 24, 1879.

HALL, WM. R., 1st Lieut. and Asst. Surgeon. Upon the termination of his services at Camp Winfield Scott, W. T., to proceed to and take station at Fort Cœur de Lion, Idaho. S. O. 142, Dept. of the Columbia, Oct. 10, 1879.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 25, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Oct. 18, 1879. . .	0	10	31	3	48	31	0	0
Oct. 25, 1879. . .	0	19	34	1	36	33	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from October 22d to October 28th, inclusive, was 11, and the number of deaths that occurred was 10. The total number of cases for this year to October 29th is 1,533, and the total number of deaths, 550.

An official announcement of the Board of Health October 25, 1879, has declared the epidemic ended. It says that but little danger is to be apprehended from yellow fever by absentees or other persons coming into the city, provided the instructions given regarding the ventilation of houses, bedding, clothing, etc., have been fully complied with. The people are advised, on their return, to avoid infected districts. With ordinary prudence, it is thought there is no danger of the disease spreading from the few cases which may yet develop. October 28th, no new cases reported within the past twenty-four hours.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.—At the annual meeting, held October 27, 1879, the following officers were elected for the ensuing year. *President*, Dr. Alfred E. M. Purdy; *Vice-President*, Dr. Horace P. Farnham; *Secretary*, Dr. Frederick A. Castle; *Assistant Secretary*, Dr. Wesley M. Carpenter; *Treasurer, pro tem.*, Dr. Orlando B. Douglas; *Censors*, Drs. J. E. Janvrin, Paul F. Mundé, E. C. Segoin, D. Webster, and F. V. White; *Honorary Members*, F. D. Lente, M.D., of Saratoga, N. Y.; John S. Billings, M.D., of Washington, D. C., and Gaetano La Loggia, M.D., of Palermo, Italy.

The Committee on Prize Essays awarded the prize to Dr. Samuel Sexton, of New York.

MEDICAL DEPARTMENT OF YALE COLLEGE.—Among the recent changes made in the faculty of the Medical Department of Yale College we notice that Dr. Matthew D. Mann, formerly of this city, has been appointed "Clinical Lecturer on Gynecology."

The annual meeting of the French Association for the Advancement of Science took place at Montpelier during the week from August 28th to September 4th.

DR. JOHN JAY ABERNETHY, Medical Director U. S. N., died of cardiac disease, in this city, October 28th, aged seventy four years.

Original Lectures.

CLINICAL LECTURE ON MANIA :

BEING THE FIRST OF A COURSE OF FOUR CLINICAL LECTURES UPON THE DIAGNOSIS OF INSANITY, DELIVERED UNDER THE AUSPICES OF THE COMMISSIONERS OF CHARITIES AND CORRECTION, AT THE NEW YORK CITY ASYLUM, WARD'S ISLAND, BY THE MEDICAL SUPERINTENDENT,

A. E. MACDONALD, M.D.,

NEW YORK.

GENTLEMEN:—In the present short course of lectures I desire to make my remarks as practical as possible; but there are two or three points which I think it will be of advantage for me to touch upon by way of introduction, and in regard to which it is necessary that we should understand each other, in order that you may understand the various patients which I shall have the pleasure of bringing before you.

In the first place, there is, as you are no doubt aware, a considerable confusion among different authorities in respect to the terms that are constantly used in reference to the subject of insanity. For this reason, perhaps, a few definitions of common terms may assist you to a more ready comprehension of the various points which will be brought up in connection with the different forms of insanity. As to the term insanity itself, this of all others has been interpreted in the most diverse ways. Without pausing even to allude to these, I will merely say that I believe the following to be the best and most comprehensive definition that can at present be arrived at :

DEFINITION OF INSANITY.

Insanity is a physical disease which manifests itself in a departure in thought, feeling, and action from the ordinary characteristics of the individual in which it occurs.

This recognizes and embodies two points, which are very important in my opinion, viz. :

First, That it is not a metaphysical disorder, but a real physical disease : and

Second, That we are to look for the standard of comparison in the person affected, and not in other individuals or an ideal type.

There are three other terms which we shall constantly have occasion to make use of, and in regard to the exact meaning of which there is a very indefinite idea in the public mind. These are, delusion, illusion, and hallucination. They are very apt to be used indifferently ; but, while they have something in common, each expresses a distinct phase of thought. A delusion is a false or mistaken belief, and a person holding it cannot be argued out of it. Illusions and hallucinations, on the other hand, are mistaken perceptions of the senses, and the subject of them firmly believes that he sees, hears, or smells something which has no existence in reality ; but, while an illusion originates in something that is actually appreciated by the senses (although it becomes distorted into something totally different), an hallucination originates in nothing. For instance, an individual suffering from illusion may look at plants or other inanimate objects and imagine that they are human beings ; but one who is the subject of hallucination does not require the presence of any such object in order to have his morbid perception.

The differences in regard to the use of terms, and also as to the nature of the various forms of insanity, extend throughout all the treatises on the subject, and each writer has his own classification. In some works pathological differences are made the basis of this, and if our pathological knowledge in this department were only sufficiently far advanced, it would probably be the best one of all ; but, unfortunately, this is not the case. Others base their classification on etiology, and others again on physiological, physical, and metaphysical characteristics respectively. For my own part, I prefer to be guided in this respect by the general drift of the symptoms observed ; and, in pursuance of this plan, we recognize four forms of insanity.

CLASSIFICATION OF INSANITY.

These are, mania, melancholia, dementia, and general paresis. The last has been added comparatively recently ; but the others constitute the natural system which has been in vogue for many years, and has been adopted by many of the best authorities. Before proceeding to the subject proper of to-day's lecture, I will point out to you examples of each of these forms, and mention a few of the prominent characteristics pertaining to each. If you will look at this row of men sitting upon the bench before you, you will, I think, at once notice two things : *first*, that they are different in their general appearance from ordinary sane individuals ; and *secondly*, that they differ very greatly among themselves. In the eight patients now present there are two belonging to each of the above forms. The first couple to which I call your attention are the subjects of

MANIA,

and I should like you to notice the marked contrast which they present in their whole aspect to the couple next them, who are affected with melancholia. Taking one of the first class as an example, we find that the man is all activity. He is constantly thrown out from himself, as it were, and notices everything that goes on around him. Hence, he is perfectly willing to converse freely, and will readily answer any question that is put to him. He is very quick in his movements, and altogether presents a very good example of the sthenic form of insanity. When questioned as to the manner of his coming here, he gives, as you hear, quite a lively account of his being arrested and charged with being drunk and engaging in disorderly conduct, and he does not hesitate to say that he would become intoxicated again if he only had the chance.

On the other hand, the man next him, who is suffering from

MELANCHOLIA,

presents an example of perfect stolidity. This is the asthenic form of the disease, and you see at once the great difference between the two patients, in their whole appearance and all their actions, as well as the tones of voice when they speak. The first is always hopeful (which is, indeed, characteristic of mania), while the second is just the opposite of this, and is constantly in the depths of despair. He is completely wrapt up in his own misery, and is too much absorbed in himself to notice anything around him, unless it should happen to concern himself also. One of the great troubles of such subjects is, that they believe that everybody about them is trying to kill them or injure them in some way. Yet, notwithstanding this, it is very common for them to attempt to destroy their own lives. It is true, as he says, that this patient made such an attempt ; and you will notice with what char-

acteristic indifference he speaks, and how low and sad are the tones of his voice. He cut his throat with the intention of committing suicide, and was sent to Bellevue Hospital for treatment. On his recovery he was pronounced insane, and sent to this institution. In my experience, almost every individual suffering from melancholia at one time or another either attempts suicide, or manifests a very strong desire to do so; and this is the case with a large proportion of all the patients who are admitted here, the attempted suicide usually being the immediate occasion of their being sent to the asylum. In the present instance there is the history of a hereditary taint of insanity; and this, I believe, would be found to be the case in almost all others if we could satisfactorily trace the origin of the disease.

There is another point which is exceedingly common in the history of insanity, and that is the element of intemperance. In both these cases—the one of mania, and the other of melancholia—it has been ascertained that there was prolonged addiction to the use of alcohol, and in this institution, where the patients belong almost exclusively to the lower classes, intemperance stands to a greater or less extent in a causal relation in from seventy-five to eighty per cent. of all cases that come under observation. The ordinary history in the case of many of our patients is, loss of work, partial starvation, resort to intoxication, then chronic alcoholism, and finally insanity.

The four principal points of interest about this case of melancholia, therefore, are the hereditary tendency, intemperance, the attempt to commit suicide, and the fact that the patient thinks that everybody about him is trying to injure him. He suffers from delirium, which is like a dream in the circumstance that he is always present himself, while all that happens in it is immediately connected with his own personality. He being thus the starting-point and centre of all, those who stand in the closest relationship to himself naturally become involved in what he imagines also; and hence such a patient is very apt to imagine that those nearest and dearest to him are trying to work his ruin. This shows the importance, in the treatment of cases of this kind, of promptly removing them from the surroundings to which they have been accustomed, and placing them in entirely different circumstances.

The third form of insanity to which I shall call your attention is

DEMENTIA.

This differs from the other two forms which have hitherto engaged our attention, in the fact that in this condition there is really a loss of mind. In the others it would not be proper to say that a patient has lost his mind, because it is often more active than in its normal state; although in a wrong direction. Dementia is usually a terminal form of mental disease, into which the patient drifts from some other variety. Hence it is ordinarily designated as secondary dementia. There is also another form, known as primary dementia; but this is comparatively rare. When it is met with, it is, as a rule, in young persons, and results from some abuse.

The characteristics of dementia are mainly physical. The subjects of it take no notice of what is going on around them; but many of them eat and sleep well, and enjoy excellent general health. Others, however, pay no attention to the ordinary wants of nature; while some have to be tended in every possible way, like infants, from the time that they awake in the morning until they are put to bed at night. In certain instances we find what is known

as the "lay-figure condition," in which the patient will remain indefinitely in whatever position he may chance to be placed. The case which I now present to you as an example of dementia is not so far advanced as some others which we have in the institution; but still he exhibits, in a sufficiently well-marked manner, most of the prominent features of this form of insanity.

The fourth and last form, as I have mentioned, is

GENERAL PARESIS.

It is only within the last thirty years that it has been recognized at all in this country; but it has been known for a considerably longer period in Europe. In the United States it is found indeed principally upon the eastern sea-board, and in New York, I may say, is far more common than in any other locality. In this asylum, therefore, there is a larger proportion of patients suffering from it than in any other in the country. In the present course I shall pay special attention, then, to the subject of general paresis; *first*, because it is a recent disease; *secondly*, because it is one that is constantly increasing; and *thirdly*, because this hospital affords so many excellent examples of it.

As a general rule, patients suffering from it are happy and contented, and everything connected with them, according to their belief, is on the grandest possible scale. Thus, they have the highest opinion of themselves, and their minds dwell on ideas of vastness, as enormous wealth, immensity of space, and unlimited periods of time. There is one peculiarity in the physical manifestations of the disease that is very characteristic, viz., a difference in the size of the pupils; and so marked and constant is this point that the diagnosis may sometimes be almost entirely based upon it. Thus you will notice it in the patient to whom I now call your attention. He is a man of fine education and extensive reading, and he will himself give you some little account of his history and what he has accomplished. (The patient was about fifty years of age, and talked very fluently. During the course of his remarks he stated that no such man as Shakespeare had ever lived, but that he himself was really the author of the works attributed to him, and that it had taken him four hundred years to write them. His plan had been to collect the sayings of the wisest men that had ever lived, such as Solomon, Pliny, Solon, Diogenes, and Bacon, and by combining these he had been enabled to compose the immortal dramas known as those of Shakespeare. The profits from these works would by this time have amounted to many million dollars (to show which he entered into a somewhat abstruse calculation); but, unfortunately, he had been robbed by unscrupulous persons of all the vast sums due him. Still he had a firm belief that all the money would yet be refunded to him. When asked who he was, he said that he was the son of Pope Pius the Ninth, and was eighty years old; and when the inquiry was made how it could have taken him four hundred years to write Shakespeare when he was only eighty years of age, he explained that he had existed in a previous sphere for trillions of years. He mentioned, in addition, that he expected to live for many ages yet to come.)

But, to return to the subject proper of to-day's lecture—mania. This may be subdivided into three forms: acute, recurrent, and chronic.

ACUTE MANIA.

The first of these is characterized by a sudden attack, which lasts but a comparatively short time. On account of the extreme violence of the symptoms, it

must necessarily terminate quite quickly either in death or recovery.

RECURRENT MANIA.

In the second form we have acute attacks recurring from time to time, and these are apt to come on at shorter and shorter intervals, until the affection glides into chronic mania.

CHRONIC MANIA.

In this, the mania may be chronic from the commencement, or may have become changed from the recurrent to the chronic form, as just stated. In it there are not the same delusions as in acute mania; nor are its manifestations by any means so violent. We have here passion, arising from disease, and more prolonged in its action.

Acute mania has been divided into two forms—that with delirium, and that without delirium. It is probable, however, that the difference is more in the patients than in the disease itself. Those subjects which are young and active usually exhibit the first variety, and those older and more infirm, the second. The prominent feature in all acute mania is sleeplessness. In almost every instance of insanity there is a longer or shorter period of depression; but it is a fact that it is more brief in mania with delirium than in any other form of the disease, so that it may escape notice altogether. The attack usually comes on at night, and from the first there is an utter absence of sleep. The whole course of it must necessarily be a matter of a few days only, as the powers of the patient would inevitably succumb if it were prolonged to a greater period. Frequently such a patient will go entirely without food, because he is so busy with thinking of the subject that preys upon his mind that he cannot spare the time to attend to anything else.

ACUTE MANIA WITHOUT DELIRIUM

is neither so sudden in its onset nor so active in its manifestations. Consequently, the patient sleeps more, and is not so violent as in the first variety. Patients affected with this, it has been noted, often have most voracious appetites, while they are filthy in their habits, and seem to delight in destroying their clothing and whatever else they can lay their hands on. They are not only mischievous, however, but are also frequently treacherous in addition.

Where there is recurrent mania, the patient between the attacks is apparently quite well and rational, and the interval between them is sometimes as long as one or two years. A certain periodicity has often been noticed about the attacks. Thus, where they recur on an average once in a year, it is found that they make their appearance about the same season each year; and when they return more frequently they are apt to come every three months, for instance. In this form of the disease a hereditary taint is almost universally met with, and we naturally look for a fatal termination, after the affection has finally lapsed into chronic mania.

Chronic mania, as has previously been stated, usually follows some other form of insanity. Ordinarily this is acute mania; but in exceptional instances it results from melancholia and other varieties. According to the laws of this State, that is called acute insanity which has continued for less than one year; while chronic insanity is that which has existed for more than one year. Personally, however, I prefer another than this division, and that is one which is based on the symptoms. In chronic insanity there are by no means as many delusions as in acute. As a

general rule, indeed, the patient gradually settles down into two or three delusions, and perhaps but a single one. Hence arises the idea of monomania; but I must say that I do not believe in this at all. I have never yet seen a case in which the patient was really insane upon only one point, and perfectly sane in regard to all others. The case which I now show you is one of acute mania which has improved very much of late, and this next one is an instance of recurrent mania; while all the others at present before you belong to the form of chronic mania. In them the delusions have become considerably narrowed down, and you notice the marked change that has taken place in their features. The hair even has changed its character; being now straight and wiry, and having assumed what is known as the "electric condition." In many of these patients we find a certain incongruity about the countenance, one part of it expressing one emotion, and another, another, which is due to a lack of unity in the action of the various facial muscles. It is a curious fact that while each patient is unconscious of his own infirmity, he believes that the others are insane, and, thinking himself perfectly rational, will often ridicule their actions. Such patients are usually fond of ornaments, and will decorate themselves with scraps of bright colored paper or anything else that comes in their way. There is one prominent characteristic that is met with in them all, and with which you cannot fail to be struck on entering into conversation with them, and that is, the utter incoherence of their language. (The last patient presented was one of chronic mania, in which the distinguishing feature was a passion for inventing so-called astronomical instruments, over which the man would spend a vast amount of time and labor, involving apparently the most extensive calculations. After this the gentlemen present were invited into the wards by Dr. Macdonald, where they had an opportunity of personally conversing with patients affected with chronic mania. Among these we noticed one whose chief delusion was, that he was a full brass band of over a hundred pieces, and whom it afforded great delight to march at the head of a squad of his companions; while another imagined himself an opera singer of world-wide reputation.)

Original Communications.

STATE MEDICINE.

By HENRY H. LYMAN, M.D.,

PROFESSOR OF PHYSIOLOGY AND OF THE DISEASES OF THE NERVOUS SYSTEM, RUSH MEDICAL COLLEGE, CHICAGO.

To the legitimate work of health boards and of sanitary officials no one can make the slightest reasonable objection. Remarking the fact, however, that our sanitary authorities are continually advocating and undertaking measures which conflict with the ethical ideas of ordinary plain people, I have sought to ascertain whether there might be in the hidden essence of things any reason for abjuration of the moral law in behalf of public health. I find, however, that the men whose ideas are most esteemed by the progressive portion of mankind—the philosophers who lead enlightened thought—have for the most part placed themselves on record in downright opposition to many of the pet schemes of our enthusiastic friends. These far-seeing thinkers continually convict our philanthropists of confusing things which should be kept separ-

ate—as, for example, the private sphere of individual energy and the public domain of communal activity, the duties of every-day life and the conduct of emergencies, the treatment of endemic diseases and the management of imported epidemics, etc., etc. For want of clear notions on these and other kindred topics there is an immense lack of well-considered effort, joined with much blind swinging of clubs in the dark, to the great discredit of all who have occasion to concern themselves with matters pertaining to the public health. I have, therefore, thought it worth while to outline a scheme of conduct which shall not so glaringly contradict the fundamental laws of utility and of right, to which so many seem indifferent.

It is useless to attempt a discussion of the duties of the State in reference to the health of its subjects, without first ascertaining clearly the province of government, and the limits beyond which its functions must not be exercised, if the welfare of the community is to be kept in view. Different theories of government are clamorous for recognition, and it is necessary to have a decided opinion regarding the relative merits of these rival theories, unless we are content to remain in doubt and darkness concerning the results of the differing modes of action which will follow our choice between opposing ideas. First and oldest, is the theory of individual government. Every man a law to himself. This is the method of a perfect state of existence, and does indeed express the highest ideal at which humanity can aim. This in its lowest form is the law of the inferior creation, and it is sufficient for the perfect guidance of all creatures and things which are destitute of will and are without freedom. The unerring movements of such things are always obedient to the necessities of their structure and physical nature, consequently they can never go wrong. But when man is set free to choose between the various paths which lie before him, though he ought always to move with invariable obedience to law, he continually fails, through ignorance or through wilfulness, to obey every law of the universe. This disposition becomes more apparent as he is brought in contact with his fellows; and the experience of all ages and of all nations proves that man cannot safely be left in all things to his own guidance: he must have some kind of a governor to keep him out of conflict with his fellow-men.

Emerging from this universal necessity we discover the development of family government and its expansion into patriarchal or tribal dominion. Here the will of the patriarch gives law to the tribe. It is a supreme, personal, human, and therefore capricious authority. It is capable of great efficiency, and has often inspired great respect, even enthusiasm, among its subjects. But, owing to the weakness of human nature, such control cannot bear with any degree of uniformity upon the people, and, as the tribe expands into a nation, the central authority either ceases to restrain or else it ripens into an arbitrary despotism. Of this form of government the world has shown and can still exhibit many well-perfected examples. The intelligence with which such a form of government may be administered is of course exceedingly variable, running all the way down the scale from the empire of Russia to the kingdom of the Zulus; but the same theory inspires each administration, namely, the doctrine of the right of the sovereign power to dictate in every particular the behavior of its subjects. Nor is this doctrine confined to the civil power. It is the central thought of the majority of religious systems; it is the belief of the priest who presumes to guide the conscience of his disciple, prescribing for every

man what he shall do to be saved, and what he shall not do if he would avoid penance and punishment at the hands of the Church, in this world as well as in the next. By a natural affinity these kindred powers in Church and State have drawn together, and, supporting each other, have ruled the world most beautifully—in theory. With what success in fact, history abundantly shows.

Against this paramount sovereignty there have been, however, in all ages, attempts at revolt. Only slaves do not resent such interference with the right of private judgment and independent action. Accordingly, with the progress of the race, and with the evolution of high moral sensibilities among the people, came a spirit of revolt. For more than three hundred years the soil of Europe has been the scene of armed protest against the presumption of the Government in State and Church to regulate the life of the subject. This conflict, though greatly prolonged and hindered from the attainment of its full fruition by the continual abandonment of the field on the part of the most enlightened portion of the people who seek liberty in this favored country, has gone on with varying degrees of success; but through the smoke of battle shines the angel of Freedom, whose form is becoming every day more clearly revealed.

Upon the American continent the French colony of Canada and the English colonies in New England have displayed the finest possible contrast between the rival institutions of Despotism and of Freedom. The English colonists were rebels against the tyranny of their government. Finding no peace at home, they exiled themselves beyond the reach of the laws which they could not and would not obey. They governed themselves, though in no very ideal manner, still in a way that was far removed from the irritating intrusiveness of the government from which they had escaped. The consequence was, a vigorous and manly growth, which has produced the happiest race the world has ever seen.

In Canada everything was ordered after a different plan. The king was supreme. He planted the colony. He prescribed its laws, and regulated its minutest concerns. Only true believers in the royal creed might set foot upon that Christian soil. With every cargo of colonists must sail a religious inspector—a priest—who should convert or drown all heretics before they reached the St. Lawrence. By the side of the royal Governor stood the Bishop; and their decrees must be obeyed. Every one must know his place and do his appointed work.

“You shall hold the first place at the Council. This man shall march at the head of every procession: that man shall bring up the rear. Jacques shall catch fish, but he may sell them only to the royal agent at Tadoussac or at Quebec. Simon shall have so many acres of land for his corn, and shall be hanged if he goes a hunting in the woods. Jean shall be a soldier, and shall fire his gun and roll the drum when I take the sacrament in the cathedral church. No one but the royal monopolist shall buy furs from the Indians, and he shall buy at the royal price all that are offered for sale. All must get married and have children—lots of them—for the country needs population. Bad women shall go back to France, for we must all confess regularly to the priest and be good. Fear God, and honor the king!”

Thus the little colony was managed. Everything was ordered in accordance with the will of a sovereign who exhibited the utmost interest in his children, whom he had commissioned to occupy the American continent for the glory of God and the welfare of

France. Strange to say, the result was an utter failure. Taught to rely upon the king for everything, the colonists would not help themselves. Hampered by a thousand petty restrictions, the Indian trade, which was the life of the colony, found its way to Albany and to Boston. Annoyed by the priests, and educated to believe in the efficacy of the sacraments of the church as a final expiation of all sins, the more energetic youth of the colony, unterrified by the penalties which were levelled at them by the royal mandate, threw off all restraint, and betook themselves to the woods, where they surpassed the savages in the license of their lives. When at length the rival powers of France and of England grappled in conflict for the possession of the continent, but one result was possible, and the institutions of freedom emerged victorious from the trial.

History is rich in similar illustrations of the blighting effects of paternal government. The annals of Ireland are one long commentary upon the unnumbered woes which are caused by the intrusion of government into the private life of the citizen. The records of the Romish Inquisition exhibit the frightful calamities which follow every attempt on the part of even the best of men to regulate the belief and the conduct of their fellow-men. And yet man cannot dispense with government. Some form of control must be devised. A central power with definite functions and limited prerogative is what is needed to secure the equal rights of every citizen. Such security insures the right of every one to perfect liberty just as far as that liberty can exist without encroachment upon the similar right of every other individual. Good government, therefore, consists in the preservation of an exact equilibrium in the relations of man and man as members of a community. Government ceases to be good, and becomes an evil, just as soon as it transcends this function and undertakes to regulate the private life of the individual.

Leaving, now, the realm of abstract thought, let us descend again to particulars which may illustrate the foregoing doctrine. The government of a city promotes the welfare of its citizens when it provides a police force to keep the peace and to protect the lives and property of its citizens; when it raises money by taxation to maintain courts of law, to extinguish fires, to clean the streets, to abate public nuisances, and to provide against such emergencies as may occasionally threaten the welfare of the community. Limiting itself thus to a control of the public life of citizens, the government—whether monarchical, oligarchical, or democratic, it matters not—will secure for all the highest degree of happiness and prosperity. When, on the contrary, the government undertakes to dictate concerning the private life and relations of citizens, the most democratically fashioned institutions may become instruments of a tyranny unsurpassed by that of the Grand Turk himself.

Keeping these premises clearly in view, it becomes perfectly easy to decide how far the State may concern itself with what is called the public health. Over all highways, by land or by sea, over the public grounds and the public buildings of the commonwealth the jurisdiction of the government is perfectly clear. The common air and the common water are left to the control of the State, which, therefore, has the right to interfere with all artificial nuisances which may infringe upon the universal right of citizens to enjoy such air and such water in their native purity. Buildings, like churches and theatres, which are used by men in their public association with each other, may justly be controlled by the State in all that

is needful for the security of citizens. But the apartments of hotels and of tenement-houses, and the ordinary residences of people are used by men in their private capacity, and therefore may not be justly invaded by the State. Honest private citizens in their own homes should be perfectly secure against any intrusion on the part of the government. In every well-ordered State there should be a medical officer to supervise the public relations of citizens, and to act as the adviser of the government in sanitary affairs. It should be his duty to prevent all damage to the health of citizens from the condition and use of the public property of the commonwealth. He should be prepared to act intelligently and promptly in all those sudden emergencies to which the ordinary existence of the community cannot be readily adjusted—such as an invasion by cholera, or yellow fever, or the plague. But it should be clearly understood that *for all the ordinary conditions and incidents of the life of a commonwealth the ordinary resources of the community are sufficient*. A State, a city, a family, will be as healthy as its individual members know how and can afford to be. Sanitary officials must cease their efforts when the line which divides the public life of the citizen from his private life has been reached. Otherwise, their control becomes at once intrusive, vexatious, and productive of evils greater than those which they seek to prevent. The old doctrine that every man's house is his castle is as true in matters pertaining to health as it is in affairs of politics or of religion. Government has no more right to compel a man to make his home healthy than it has to compel him to make his home religious. There was a time when it was thought right to subject men to fines, imprisonment, torture, and death, if they would not regulate their belief and their private life in accordance with the dominant creed of the State. But we now see clearly that such severity is not only wrong, but that it is subversive of the very object in view. And yet, in spite of this experience, there is a class of men—it is to be regretted that some of them are called physicians—who are clamoring for the revival, so far as sanitary matters are concerned, of those inquisitorial powers which made civil and religious authority so hateful to our ancestors. Strange as it may at first sight seem, it is true that in one of the freest countries in the world some of the descendants of the men who by force of arms wrested liberty from the tyrants of the Old World, are now the most reckless assailants of the liberties which were so painfully secured. This fact, however, is only another illustration of the working of natural laws which are beyond the control of human power. Just as disease invigorates the race by weeding it of its weakly members, and as persecution purifies the church, so tyranny stimulates the spirit of freedom. When, by a triumphant outburst of liberal principles, that irritant has been removed, the jealousy with which individual rights have been defended soon languishes, and a few generations suffice to produce a feeling of indifferent security which once more favors all the insidious approaches of the worst forms of despotism. It matters little what the form of government may be. When that vigilance, which is said to be the price of liberty, has once relaxed, the most democratic institutions will lend themselves as readily as the most aristocratic to the work of subverting the liberties of the people. Facts like these should make us cautious and suspicious of the new-fangled methods which certain enthusiasts are so noisily urging upon the public under the guise of philanthropy and zeal for the welfare of the race. In an eastern city, for example, we are told (*Chicago*

Med. Jour. and Ex., May, 1879, p. 515) that, if he could, the chief medical officer of the city "would have every house in which scarlet fever existed guarded by a policeman, whose duty it should be to see that no one but the physician entered or left it until quarantine was removed. Supplies of food would be left at the door." Turkish ignorance and Russian barbarism could not do better! Ignorance I call this, because of its total blindness to the great fact that such endemic diseases are the beneficent agents of that natural selection by which the vigor of the race is maintained. We hear a great deal about the higher education which is claimed as the peculiar attribute of the Athens of America. If that is its legitimate outcome, the less we have of such higher education the better off we shall be. In fact, however, such notions are not the product of high education; they are the result of superficial knowledge and of a failure to comprehend the final causes of disease. They are survivals of mediæval barbarism, and they will vanish like the morning mist before the advance of real education in the realm of natural and social sciences.

We shall, in this connection, find it worth while to consider the results of the method of dealing with scarlet fever by the government, which has been attempted in certain cities; and we speak of scarlet fever because it is the most familiar example of an endemic infective disease which exists in our communities. Physicians are required to report every case to the local health officer, who then undertakes to "stamp out" the disease by nailing a placard upon the infected house. To the utter astonishment of the pin-hole philanthropists, who kindly introduced this novelty, it is received with the greatest discontent by the majority of citizens. Many causes combine to produce this feeling, but chiefest and best of them all is the deep and, let us hope, ineradicable sentiment of hostility to that intrusion by the State into the private life of the citizen, of which the placard thus affixed is the detested symbol. It is not so much the thing itself as the thing it signifies, which is so detestable. The failure to effect any good results by such intrusion is, moreover, admirably illustrated by the same experiment. When people find that the misfortune of illness is likely to bring upon them the additional evil of governmental invasion of their domestic affairs, they are slow to invoke the aid of the physician who finds himself compelled, even against his will, to act as the agent of the State. He, too, when finally summoned, often acts with deliberation. He waits, to be sure of his diagnosis. He transmits the obligatory message through the most dilatory channels. Oftentimes he yields to the solicitation of his patron, and without compunction violates a law which his judgment condemns. Nor is this wrong, for the lower law must always yield to the higher. The occurrence of disease is thus concealed, and the chances of its unsuspected propagation are increased. Consequently the statistics of localities where this intrusive method prevails have disclosed the complete failure of every attempt to limit scarlet fever by State intervention. Stringent measures invariably defeat themselves. This fact, however, will only be regretted by those who have not yet learned to comprehend the meaning of disease and its relation to the evolution of the human race. The British Medical Association, through its recent action (*Brit. Med. Jour.*, Aug. 16, 1879, p. 256) in opposition to the demand of certain local authorities for compulsory registration of infectious diseases, has exhibited a comprehension of the situation worthy of imitation throughout the civilized world.

With the results of such official intrusion let us now contrast the outcome of an ideal management which has learned to respect the division between the public life and the private relations of the citizen, and which recognizes the sacred duty of the State to abstain from interference with those private relations. Under such administration there is no fear of official intermeddling. The occurrence of infectious disease is at once confessed by every family, and the neighbors are put on their guard. Advised by their physician, they will generally consent to place a notice of sickness at their door. Stimulated by a proper fee, paid by the commonwealth, the attending physician at once forwards, by the hand of the householder, who is thus made the responsible party, a notice to the health officer, who passes on the notification to the public school, from which all infected children are thus easily excluded without an opportunity for the expression of the slightest feeling of resentment against the authorities. In this way the public health can be much more effectually protected than is possible under the intrusive system.

At this point in the argument we find ourselves confronted by the almost unanimous contradiction of the official class. They fancy that such lenient measures would be inefficient. They model their conduct after the traditions of despotic governments in Europe, and insist upon the superiority of the results of such methods. It is perfectly natural that they should thus advocate everything which tends to magnify official position and function. Men love power, and seek eagerly for justification of its use. Right here is one of the difficulties with which civilization is obliged to contend. A large proportion of the officers to whom the care of the public health has been confided are men whose only training has been gained in the camp and on the field of battle. They are, too often, men whose years have stiffened their prejudices into a rigidity which incapacitates them for rational discussion of social problems. With little experience of civil life and of the sympathies which should grow out of daily intercourse with the sick, they are peculiarly liable to go astray in the wake of any enthusiast who may chance to stir the sluggish current of the official pulse; and they rarely seek to correct the extravagances of dominant and fashionable hypotheses by consultation with the great mass of practical workers in the medical profession. Too many of their public and official utterances are marked by utter indifference to the constitutional rights of the citizen, and seem only to "breathe out threatenings and slaughter" against all who venture to question their wisdom. It is the exhibition of traits like these that has divorced so many of our prominent sanitarians and philanthropists from the sympathies of the majority of the medical profession throughout the country—a result which cannot be too greatly deplored. It, therefore, cannot be wise to set up such a class as judges of what is right and expedient in the management of the public health. They may appear as advocates at the bar of public opinion, but the experience and thought of an enlightened world must constitute the judge. Such experience shows that every intrusion of the State into the private life of the citizen, whether in the realm of politics, or religion, or health, invariably results in the production of evils greater than those which are marked for suppression. Consider the fate of every attempt to annul the evils of prostitution by a rigid state of inspection of harlots. Though disease may for a brief period seem to diminish, the luxury of manners and the reckless disregard of consequences which are directly fostered by the State, whenever it

thus undertakes to protect its citizens against their own ignorance and folly, soon suffice to swell the volume of disaster beyond its original proportions. This fact is now pretty generally recognized in the adjustment of the relations of the State to the matter of prostitution—a result which we owe to the attention which it has received from the ablest minds in the community. Could the same ability be thrown into the discussion of the relations of the State to other communicable diseases, we should soon be rescued from all fear of the despotic measures which ordinary sanitarians seem determined to saddle upon us.

The adoption of the principles which have now been set forth will not in the least conflict with the assumption and exercise of extraordinary powers by the State in the presence of extraordinary emergencies. In matters pertaining to such emergencies the old maxim, *inter arma silent leges*—military necessity knows no law—is perfectly true. But the forms of pestilential invasion to which a given community is occasionally liable are well known, and are few in number. During the prevalence of cholera, or yellow fever, or the plague, the State may properly display an energy commensurate with the virulence of the enemy, just as the army of the nation should be used against foreign enemies, or in case of insurrections; but the preservation of domestic tranquillity should be left to the ordinary police officials of the country. But, as in time of war we urge our generals to actions which would be criminal in time of peace, so in times of epidemic invasion our sanitary officials may be suffered to enjoy a license which they may not rightfully claim during the ordinary course of events. We need in every commonwealth an enlightened official who shall supervise the *public* health, and who shall be prepared to take the lead in every sudden and overwhelming emergency, but who shall always recognize the fact that by careful abstinence from interference with the *private* health of the citizen he can best serve the highest interests of the community.

Keeping these principles in view, our new State boards of health should find no difficulty in defining their powers and their functions. They may rightfully provide for quarantine upon the borders. They may regulate thoroughfares and public places throughout the commonwealth. They may cause the destruction of diseased animals and tainted provisions which have been made the property of the State; but they have no right to make away with such things until they have ceased to be the property of private individuals. They may—if such a course receives the sanction of their professional brethren—promulgate and enforce the educational conditions in accordance with which physicians shall be admitted to the practice of medicine; for these matters concern the public life and intercourse of citizens. But the relation between a physician and his patient is domestic and private; consequently, so long as that relation involves nothing criminal, no public official has the slightest right to invade that relation. No matter how unskilful or unprincipled the doctor, no matter how foolish the patient, it is their own private affair, and they alone should be responsible for the result. If either party is dissatisfied with the other, there are courts of law in which they may adjust their differences. Beyond affording such facilities, the State has no right to interfere.

Whether a board of health may undertake the collection of information regarding the vital statistics, or the sanitary topography of the country, is a question for the legislature to decide. If the State can afford to pay for the collection and circulation of such in-

formation, there need be no objection to the effort. But if a legislature cannot find means to defray the expenses of such work, it should not be done, and it could not be attempted without immediate and direct invasion of the private rights of citizens. There is no more justice in compelling physicians to make such returns than there would be in forcing them to see that every dying man left his will in proper form.

It is, of course, too much to expect that the doctrines here advanced will be acceptable to those who have abandoned themselves more or less completely to socialist theories of the function of government. The political institutions of Europe are for the most part based upon such theories, the only question about them being whether the commune shall be administered for the benefit of aristocrats, or for the emolument of day-laborers. The taint of such doctrines is infecting much of our own hasty legislation, and will result in unnumbered future evils unless it is met with courageous determination. For this reason I have thus sought to direct attention to the great principles upon which every free government must depend.

AN INTERESTING OBSTETRICAL CASE— THE LIVER PRESENTING.

By A. L. SWEET, M.D.,

SOUTHOLD, N. Y.

I was called, October 12th, to see Mrs. H—, a large, masculine Irishwoman, who was supposed to be in labor. The nurses in attendance assured me that the waters had broken some time before. A short time after entering the house I made an examination, and, to my surprise, found a soft, spongy mass occupying the vagina. It was about four inches long, irregular in shape, with an average diameter of perhaps one and a half inches, and so fragile that I could easily tear it with my fingers. I at first concluded that I had a case of placenta previa, and that a part of the placenta had been extruded from the os, although the feel was not exactly like that of placental tissue, and there was no hemorrhage. I was still further mystified when, upon passing my finger higher up, I could find no place where the supposed placenta was attached to the uterus. I could sweep my finger clean around it, and, in making traction on it, it seemed to be firmly identified with the uterus. I also found that the breech was presenting. Being very much in the fog as to the nature of the case, I predicted a still-birth and administered some ergot (as the pains had nearly died out), and awaited the course of events. In due time the child was born, and, after its birth, I found that what I had supposed to be the placenta was the *liver of the child*. The fetus was a small one, justifying the opinion of the mother that she was in labor before her time—was dead, and was a monstrosity. The lower part of the pelvis was undeveloped, being covered only with a thin membrane, and upon the first contractions of the uterus had allowed the contents of the abdominal cavity to escape; so, upon the birth of the child, the liver and intestines were all out of the body. The head and upper extremities were perfect, but the legs were joined to the left side of the trunk at a right angle. Upon the right thigh, about three inches below the trochanter major, was an excrescence about half an inch in length, which I suppose to have been a rudimentary penis, as there were no other signs of sex to be seen anywhere else. There was an anus at the usual place, and a short portion of a rectum. The woman is the mother of three healthy children.

A CASE OF EPITHELIOMA OF THE VULVA SUCCEEDING A LONG STANDING PRURITUS—OPERATION—CURE.

By ELIZABETH M. CUSHIER, M. D.,

NEW YORK.

THE following case presents, it is believed, more than one point of interest:

1st. In the development of an epithelioma in a comparatively rare situation.

2d. In the possible relation of cause and effect between it and the pre-existing pruritus, whether we regard the neoplasm as the result either of injury done to the tissues by treatment of the pruritus, or to the mechanical irritation resorted to in order to allay it. The patient was first seen in Dec., 1878, and gave the following history: Mrs. D—, aged 60, mother of three children. Menstruation ceased thirteen years since. Her health had always been good up to the time when present history begins. Ten years since the patient began to complain of itching of the vulva. This continued to be more or less troublesome, without materially interfering with her health, until about two years ago, when it became much more severe, depriving her of rest at night. During the past six months she has had more frequent attacks of the pruritus during the day, and at night has been obliged to obtain what rest she could by sitting up in an easy-chair, as the itching became intolerable upon going to bed. She complains also of a soreness of the vulva, which she dates from an application made some months previously. She is extremely nervous, trembles and cries when spoken to, and is evidently suffering from loss of sleep. Her appetite has failed, and her strength very much diminished.

The patient has been under treatment during the past two years without benefit. She says she was seen some months since, in consultation with her own physician, by an eminent gynecologist of this city, at which time the vulva was "burned."

The patient was taking, when first seen, morphia powders, but without much relief, as she awakened constantly from the slight dozing which they produced. She was also using a lotion containing carbolic acid. There was no history of leucorrhœa in the case. Upon examining the vulva, both outer and inner surfaces of the labia were found to be pale and glazed. The nymphæ were hypertrophied, and on the inner surface of the right one there was an ulcerated spot about one-third of an inch in diameter, which was covered with pale granulations. The vagina was more healthy in color, and its tissues apparently normal. The uterus was atrophied. The membrane of cervix was of a deeper color than the vaginal membrane, and at the entrance to the cervical canal there was a very slight erosion. A small amount of thin yellow fluid escaped from the cervix. The canal was sensitive to the passage of the probe.

The itching was referred to the entire vulva, but more especially to the region of the clitoris and nymphæ. An examination of the urine for sugar gave normal results. The case seemed a very unpromising one, and was undertaken with but slight hope of success. The treatment was in brief as follows: Locally, applications twice a week to cervical canal, of acid carbol. and glyc., ā. Vag. injections of a one per cent. sol. of acid carbol. night and morning. Ungt. aconitifolia to be applied to vulva when itching became severe. At the point of ulceration bis. subnit. was used.

The patient was also given potas. brom., gr. xv.; fl.

ext. cannabis ind., ʒ. xv. ; tr. opii deodorat., ʒ. vii. , at bedtime, and this was repeated, when necessary, during the night. At the expiration of a week the improvement was sufficient to be very encouraging. The patient was sleeping several hours during the night, and feeling quite rested, although she had not yet ventured to lie in bed. During her waking hours she also suffered much less. At the end of the second week she reported herself as being able to sleep in bed, and her appetite was improving. From this time there was a gradual diminution of the pruritus, and at the end of three months it was comparatively slight. Indeed, the principal symptom now complained of was the soreness and pain at the ulcerated point above mentioned. This had resisted all efforts to heal. It had increased in size, and assumed a different appearance. Its surface was elevated above the mucous membrane, and showed distinct papillary projections, while the surrounding tissue had become hardened and infiltrated. There could now be no doubt that an epithelioma had developed at this point, and Dr. Emily Blackwell, who was asked at this time to see the patient, concurred in the advisability of an immediate operation for its removal. It was six weeks, however, before the patient could be persuaded to submit to such operation, and by this time the growth had increased to the size of a large hazel-nut. It occupied the upper half of the inner surface of the right nymphæ, extending very nearly to the base of the clitoris, and to the base of the nymphæ of the opposite side. The indurated portion could be lifted quite away from the underlying tissue. There was no enlargement of the inguinal glands. It was evident that the growth was limited to the right nymphæ, but on account of its close proximity to the left nymphæ and the clitoris, it was decided to remove both of the latter. The operation consisted, therefore, in the removal of the clitoris and both lesser labia, and was accomplished by lifting these structures well up from the tissues beneath and separating with scissors. The hemorrhage was not difficult to control.

The surface remaining after the removal of the above parts presented three denuded angles: one above, over the site of the clitoris, and one on each side, corresponding to the nymphæ. These were completely covered in by uniting the edges of the tissues bordering them, and for this purpose five silk sutures were introduced on each side and four above. The wound healed throughout by direct union.

From the time of the operation the patient was able to sleep without anodynes, and no complaint was made of the pruritus, while the vulva assumed a more natural appearance, becoming softer and of a normal color. When last seen, some months after the operation, the condition of the patient, both general and local, was very satisfactory, and so completely had all evidence of an operation disappeared, that the absence of the removed structures might have been supposed to be congenital.

Upon microscopic examination of the growth I found the following: papillæ composed of masses of large multiform epithelial cells, also the so-called thorny cells in considerable number. These last were either isolated or in their characteristic groups of from two to several, held firmly together by their serrated edges. There were also present the well known "pearls" which are so frequently found in epithelial new formations. The growth presented, indeed, all the characters of a typical epithelioma.

In the very few cases of malignant disease of the vulva which have been reported, pruritus has been generally mentioned as a symptom. But it still re-

mains doubtful, in at least some of the cases, whether the pruritus preceded the advent of the growth or was excited by it. Mayer,* in reporting nine cases which came under his personal observation, relates one which closely resembles the above; in which the pruritus had existed for years, resisting all treatment, and becoming gradually worse before the canceroid developed which led ultimately to a fatal termination. In most of Mayer's cases the growth existed at the time when the patient came under observation, while the pruritus only dated from a few months, and may have been, therefore, only a symptom of the developing neoplasm.

There can be no doubt, however, that irritation of some kind, here as in other localities, may play an important part in the causation of these new formations. Of the nine cases reported, as above mentioned, by Mayer, there is given a detailed account of five of them, in four of which there had been irritation or injury preceding the appearance of the canceroid, and bearing an apparently close relation to it.

In one of these cases the beginning of the affection dates from an injury done to the tissues by a badly adjusted strap attached to a hernial truss. In another, the patient, during a long illness of her husband, had sat upon the hard edge of his bedstead, often for hours at a time. At the point where pressure had been thus made upon the right labium and nates an epithelioma developed. In two cases there was, as above mentioned, the previously long existing pruritus of the part. In the fifth case it remained doubtful as to the pruritus being antecedent or coincident with the malignant growth.

In regard to the treatment of the pruritus in the case here reported, three questions are suggested.

First.—As to the influence of the aconitine, it is certain that from the date of its employment the pruritus very decidedly diminished.

Second.—As experience has shown that all local applications in these cases so frequently fail in producing the desired effect, at least more than temporarily, is it not probable that the diminution of the pruritus was due principally to the modification of the nutrition of the part as a result of the development of the neoplasm?

Third.—May not also the removal of so large a portion of the mucous surface as is included in excision of the nymphæ and clitoris, and the still further changes in nutrition due to the healing of the wound after the operation, have aided very materially in the final cure of the affection?

VIVISECTION.—The violent agitation against vivisection which has been going on in England, and which even called out an address in its defence, at the meeting of the British Medical Association, has reached New York. Mr. Bergh has appeared in print several times, and has not only denounced the vivisectioning physiologists of the present day, but is extremely severe on Galen and Harvey. Magendie he considers to have been pretty nearly the worst man that ever lived.

In the clerk's office of the College of Physicians and Surgeons there used to hang a drawing representing, we believe, the interesting process of establishing a gastric fistula; Mr. Bergh, in deep distress, being seated in the background. Underneath ran the legend:

"Shall man or beast the greater be,
Science, or false philanthropy?"

Progress of Medical Science.

PORRO'S OPERATION: CESAREAN SECTION, WITH REMOVAL OF THE UTERUS AND OVARIES.—In the hope of diminishing the mortality after Cesarean section, Porro, of Pavia, in May, 1876, proposed and practised successfully the ablation of the uterus and ovaries after the removal of the child. The operation was favorably received by the Continental gynecologists, and Fovier, of Paris, in a recent article, stated that it had been, as far as he had been able to learn, performed thirty-three times, with the result of saving more than half of the mothers. To these cases may now be added two more, which were reported to the *Académie de Médecine*, on July 29th, by M. Tarnier. In the first case, the operation was performed seven days after premature rupture of the membranes at the eighth month, and four days after the death of the child. The child and placenta were putrid, and the mother died three days after the operation, of putrid infection. Delivery per vias naturales had been rendered impossible by the presence of a fibrous tumor, which filled the excavation. The second case was successful, and M. Tarnier, in presenting the patient to the Academy, remarked that the case was especially interesting, because the Cesarean operation had not been successfully performed in Paris since 1787. In this case the operation was rendered necessary by rachitic deformity of the pelvis, which was so marked that cephalotripsy was impossible. The operation was performed the day the patient entered the *Maternité*, but the membranes had ruptured three days before, and the child had been dead two days. The cervix was not dilated. After incision of the abdominal walls and uterus and removal of the child, the uterus and ovaries were drawn out of the wound and a Cintra's serre-nœud was applied at the junction of the body with the cervix; above this serre-nœud, after the uterus and ovaries had been cut off, a transverse pin was placed, which was itself secured by a second wire ligature. The patient made an excellent recovery, the maximum temperature in the axilla being only 101 $\frac{1}{2}$ ° F. The wound was treated on the strictest antiseptic plan, and M. Tarnier is inclined to ascribe the successful result largely to this fact. He believes that the operation is not only justifiable, but that it is destined to take a front rank in surgery. It seems to him superior to simple Cesarean section, because it does away with two of the dangers of the latter, viz., uterine hemorrhage, and peritonitis from escape of the lochia into the peritoneum. These elements of increased safety will more than counterbalance the objection that the operation entails sterility on the patients. M. Tarnier dwelt urgently on the importance of having recourse to the operation early in appropriate cases, for the sake both of the child and the mother. He believed he was the first surgeon to perform Porro's operation in France, but this claim has been challenged by M. A. Fochier, surgeon-in-chief of the *Charité*, who states that he performed the operation in that hospital three weeks before the date of Tarnier's first operation. Dr. Storer, an American surgeon, is credited with having performed the first operation of this kind in 1868. The issue was fatal.—*Lyon Médical*, Aug. 17, 1879; *La France Médicale*, Aug. 2, 1879.

PERSISTENCE OF THE CANAL OF MÜLLER.—In the March and April number of the *Journal de l'Anatomie et de la Physiologie*, M. Rémy describes the post-

mortem appearances seen in the genito-urinary apparatus of a child who died in the Hôpital des Enfants, Paris, of cystitis and suppurating kidneys, the result of chronic retention of urine. In front of the right ureter another canal was found. It began as a *cul-de-sac* among a mass of little cysts close to the suprarenal capsule, and passed downward under the fundus of the bladder, opening into the utricle of the prostate by an aperture which would admit a large probe. Passing between the muscular and mucous coats of the bladder for some distance before reaching the utricle, it raised the mucous membrane close to the neck of the bladder to such an extent as clearly to have been the cause of fatal retention of urine. This abnormal canal was evidently Müller's duct, and the cysts at its upper end represented the remnants of the Wolffian body. As the duct opened into the utricle, the homology of that depression to the female uterus is practically confirmed by this case.

On the other hand, Waldeyer's theory that the hydratid of Morgagni represents a remnant of Müller's duct, is shaken by the fact that a well-formed hydratid existed on the right testicle. The theory, further, that the little body called the "organ of Giraldès" consists of the remnants of the Wolffian body, is destroyed by the fact that in this case both this organ and the Wolffian body were found separately.

The case thus, apart from its pathological interest, throws light upon three points in the development of the human body.

EXCREMENTAL DISEASES.—Under this title Mr. Geo. E. Waring, Jr., gives a very clear account of the dangers incident to the present methods of removing human excreta. Beginning with the ordinary city house, he shows that, even when perfectly plumbed after the usual methods, there is always a danger lurking in the house drainage-pipes. These pipes are never sufficiently flushed to keep them clean and free from excrement; they have no free communication with the air; consequently they generate and will always contain noxious gases and low organisms. These are kept from entering the house itself chiefly by a few inches of water, which is liable to be siphoned away, and which, in any event, is able to transmit the foul gases and nourish the noxious germs. Human excrement, therefore, is not at present safely removed from our houses by the methods now in vogue. To remedy this, he suggests that the house-drain have a free circulation of air through it, and that the water-seal traps be prevented from contact with the air of the drain.

The dangers of ordinary street-sewers are less than those from the individual house-pipes, because there is in them a constant current of water and frequent changes of air. Nevertheless, they are far from safe.

The best final disposal of the excrement is a question yet to be decided upon.

There are now essentially two methods, that of emptying it into large bodies of moving water, and that of distributing it upon the soil. The latter is much the most expensive in most cases, and is not always practicable.

The whole system of the disposition of sewage has so many dangers and defects that it will eventually have to be changed—a change, however, for which neither public opinion nor the public purse is yet ready. In the address on hygiene at the recent meeting of the British Medical Association, Dr. Fergus attributed the increase of diarrhoeal diseases and the failure to diminish enteric fever and diphtheria in the past decade, to the present method of carrying off excrement, garbage, etc., by means of water, which, he in-

sisted, was a dangerous agent for the purpose. It is considered certain that a change in our present sewerage methods must eventually be made, and it is urged by Mr. Waring that physicians endeavor to encourage and educate people to such a movement.—*Boston Med. and Surg. Jour.*, Aug. 21, 1879.

AN OPERATIVE METHOD TO COMBAT COMMENCING PYÆMIA.—H. Kraussold, in v. Langenbeck's Archives (vol. xxii., p. 965), relates the case of a patient at the Erlangen Clinic, whose leg was amputated just above the knee-joint, on account of a badly united fracture, complicated with an aneurism of the posterior tibial artery. The operation was followed by repeated and alarming hemorrhages, and the manipulations necessary to control them destroyed the antiseptic precautions, so that on the fourth day pyæmia supervened, with a chill. As the cause was supposed to be a commencing suppurating thrombus of the vein, the latter was opened, and a discolored fluid along with the contents of the thrombus escaped. Immediately after this the vein was exposed to Peupart's ligament, ligated at two points, and the intervening part, from two to three centimetres in length, removed. The femoral artery was also ligated to guard against further hemorrhage. The temperature of the body at once sank to the normal, and the patient recovered without further bad symptoms. Ligation of the vein under similar circumstances has been performed before with good results, and as soon as the diagnosis is established one would not hesitate to resort to it.—*Cincinnati Lancet and Clinic*.

FATTY EMBOLISM.—This form of embolism seems to be attaining some pathological as well as clinical importance from its occasional occurrence in diabetes, and its frequent occurrence where the continuity of bone is interrupted. Two cases, illustrating the latter fact, have recently been demonstrated by Professor Recklinghausen, and are related in the *Cincinnati Lancet and Clinic*. In the first case, death occurred about forty-two hours after resection of the carious head of the femur. The patient, a healthy and well-nourished young man, had been doing well for the first twenty-four hours after the operation; he then suddenly grew worse, and died in collapse. Macroscopically, none of the organs or tissues presented anything abnormal, and it needed microscopical examination of the lungs to account for the sudden and unexpected death. In the second case, a man forty-nine years old, there existed a very extensive chronic endarteritis, with granular kidney, and an immense hypertrophy of the left ventricle. The disease of the arteries had led to the occlusion of both tibial arteries on one side, and dry gangrene had begun to appear, when the patient suddenly died with some symptoms of apnoea. The microscopical examination showed large masses of fat in the arteries and capillaries of the lung.

According to the researches of Bush, fatty embolism of the lungs always occurs in greater or less degree where the continuity of bone is interrupted—hence, even in simple fractures. It is only in rare and severe cases, however, that the embolism is sufficient of itself to cause death.

RECENT PROGRESS IN THE SYMPTOMATOLOGY AND TREATMENT OF INTESTINAL OBSTRUCTION.—For some time past the *British Medical Journal* has been publishing articles from various prominent men, on the subject of intestinal obstruction. The discussion, aroused in this way has brought out a number of important points, and has placed the treatment of

this affection on a more definite and satisfactory basis than ever before.

Preliminary to the consideration of intestinal obstructions, a very useful classification into acute and chronic forms has been proposed by Dr. James T. Goodhart. Under the head of acute he places: 1, internal strangulation; 2, volvulus; 3, intussusception; which latter may also be chronic. Under the head of chronic are: 1, intussusception; 2, contractions; 3, strictures. Besides these there are rare cases of obstruction from gall-stones and various foreign bodies. The symptoms associated with the acute forms are sudden vomiting and constipation. The constipation is generally absolute, but there may be small passages. Abdominal distention, tympanites, visible peristalsis, all follow very soon, while the vomiting eventually becomes stercoraceous. In the chronic cases there is generally a history of paroxysmal colic for some time before the onset of the more urgent symptoms. The abdominal distention slowly increases, and reaches an extreme degree, and the vomiting and absolute constipation come on at a late period. Throughout the illness the visible muscular action is usually a prominent symptom.

It is in regard to the treatment of intestinal obstructions, and especially as regards surgical interference, that opinions have varied most conspicuously, and that the recent discussion has been most extended; nor are the authorities even yet fully united upon it. It is agreed, however, that, in cases of this kind, the first point to be observed is that of denying the patient food and drink. He should receive nothing but nutrient and stimulating enemas. He should not be given any solvents even, with the idea of liquefying the feces, for it has been determined by post-mortem examinations that the contents of the intestines above the stricture are always fluid.

The next point, as to the proper drugs to be administered, is not so clear. According to Dr. Goodhart, opium should be administered, as it not only relieves pain, but often acts in these cases like a purgative, by relieving to some extent the constriction and allowing the passage of the intestinal contents. Dr. W. H. A. Jacobson, however, in a paper read before the Hunterian Society, advises the avoidance of opium if possible, as it has a dangerous tendency to mask symptoms. There is a general agreement, whether opium be used or not, as to the great value of belladonna. In 1878, Dr. Norman Kerr published a paper giving statistics showing the efficacy of this drug. Five cases of intestinal obstruction were related, all of which got well, although three of them received two grains of the extract every hour. It is generally necessary to use very large doses.

Whatever drug may be given, a very prominent indication has, at the same time, to be considered, viz.: that of the relief of over-distention. For this purpose, puncture of the distended coil of intestine above the stricture has been recommended. Dr. W. H. Broadbent, physician to St. Mary's Hospital, relates the case of a lady who was subject to periodical attacks of intestinal obstruction due to pressure of an ovarian tumor. On five occasions this obstruction was relieved by puncturing the intestines, which were greatly distended with gas, with a long aspirator needle. No evil effects followed, in spite of the fact that twice the motion of the collapsing intestine pulled the needle so that it lay flat upon the abdominal wall. It is the more general opinion, however, that puncture of the intestine is an extremely dangerous procedure. If the distention is not at once relieved, the mucous membrane fails to evert itself and

cover the hole; consequently feces escape and peritonitis is set up. If practised at all, great quiescence of the intestine must be obtained by an extra dose of morphine; a coil of intestine containing gas alone should be selected, and it should be punctured in its highest and central part.

Should drugs fail, and puncture be inadmissible or useless, there are still left two courses to pursue: the one is abdominal taxis, the other an exploratory incision, followed, if possible, by surgical or mechanical treatment of the obstruction. More than twenty years ago Mr. Hutchinson contended that gastroto-my for abdominal obstruction was never justifiable; and, further, that, as a rule, abdominal taxis was to be preferred to an exploratory incision. The first dictum has now been conclusively refuted, and it is also pretty well established that if abdominal taxis and all other measures fail, an exploratory incision should be made. Facts, as far as they have been collected, show that an exploratory incision made under the above circumstances will not diminish the chances of the patient, and may save an otherwise hopeless case. Abdominal taxis, however, should, as a rule, be first tried; a point to be remembered is that unless done early it may increase the damage done to the constricted and already weakened intestine. In performing this taxis Mr. Hutchinson's directions are that chloroform be used, that a copious enema of water be forced, by help of a tube, into the intestines, and that then, upon escape of the water, the patient be inverted and the intestines be firmly pressed as high up as possible in the abdomen.

Should all previous measures fail, gastroto-my should be performed, under the following conditions: 1. It should be done earlier than has heretofore been the case. 2. It should be done antiseptically. 3. It should never be done when symptoms of peritonitis or enteritis have set in.

The last rule is laid down by Mr. Jacobson, but it has its exceptions. Thus, in the September number of the *American Practitioner*, a case is recorded by Dr. J. N. McCormack, in which gastroto-my was performed for internal strangulation. Upon cutting down to the peritoneum, the intestines were found agglutinated with lymph, while the strangulated part had already begun to slough. The patient recovered, however, with an artificial anus.

CONTAGIOUS PLEURO-PNEUMONIA.—This disease has recently appeared again among the cattle in Putnam County, New York, and has created much alarm there. The manner in which the disease was introduced is as yet unexplained. The first case appeared last January in a herd on the eastern limit of the county. A second herd, on the western border, became affected in July last. Up to October 9th there had been twenty-seven deaths from the disease; about fifty were then suffering from it, and from one hundred and fifty to two hundred had been exposed. Gen. Patrick, Prof. Law, and Dr. Hopkins have examined the cases and pronounce them undoubtedly those of contagious pleuro-pneumonia. The disease begins insidiously, but eventually develops the symptoms of an acute pulmonary phthisis; the lungs, upon post mortem, often showing excavations as well as hepatization.

Some attempts were made at first to prevent further infection by inoculating the healthy animals. This, however, has been forbidden by Gen. Patrick. The County Supervisors have raised sufficient money to carry out the "stamping out" process, which consists of quarantine and extermination.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

HOSPITAL PAY-PATIENTS.

OF late there has been some discussion concerning the proper relations which should be maintained between the attending physician or surgeon and the hospital pay-patient. At first sight the question would appear to be a natural and easy one to settle, but it has in reality grown into one of the difficult problems of hospital management.

With very few exceptions, all of our public institutions receive patients who are expected to pay for the accommodations and the treatment which they receive. The income derived from these sources is devoted to the interest of the hospital, and to the striking of a balance in favor of such patients admitted as paupers. This is perfectly proper when confined within certain limits. But, not content to meet the requirements of patients who are willing to pay a small sum and maintain a certain independence, the managers provide extra accommodations for patients, for which proportionably heavier rates are charged. For instance, some of the private rooms in these hospitals are held at from twenty-five to fifty dollars per week, according to extras which may be furnished in the shape of private medical attendance, private nurses, etc., and yet these patients are expected to maintain the same relationship to the medical staff, regarding pecuniary compensation, as the veriest pauper who, for the purest charity's sake, is admitted for medical treatment.

It requires no argument to prove this a flagrant abuse of medical charity. While the profession are perfectly willing to give their services to the very poor, or even to those who can do no more than pay a nominal sum for their board in a hospital, it is certainly an abuse of such generosity to ask members of the staff to give their time and attention to the treatment of patients who can afford to be luxurious, who demand private apartments, and who are able and willing to pay liberally for them.

It may with some show of justice be claimed that an institution which can, under the name of charity, provide such extras for well-to-do patients, must necessarily make the care of the sick and needy secondary to mere pecuniary considerations and to the maintenance of a first-class hotel, with medical attendance free. As a rule, when a well-to-do patient applies for admission into any of these institutions, if he is willing to pay for his accommodations, no objections are offered by the superintendent. On the contrary, the latter seems only too willing to seize the opportunity of thus increasing the income of the hospital. While it may with truth be said that the managers would not directly interfere with the receiving of a medical fee from such patients, they are so far from encouraging the practice that it is barely tolerated. So much is this the case, that it would be difficult to foretell the result should any attending physician or surgeon of the institution refuse to attend these extra-paying patients unless he received his usual fee for so doing.

It is true that the visiting staff are supposed to give their services free to hospital patients. So far as it is an act of charity, this is perfectly well understood; but a patient ceases to be an object of charity when he is able to pay fifty dollars per week for a private room. If the hospital has a right to accept such extra pay for accommodations under the name of a charitable institution, there can certainly be no blame to the physician for making a proportionate claim. And yet it is said by the hospital management that if such a precedent were allowed, an unjust distinction might be made in favor of such patients as could afford to pay the most. While this objection to a fee system might apply to nurses, it certainly could not do so to the doctor, who, while in attendance upon a case, discharges his duties with as much conscientiousness to a pauper as to a king.

It is well known that certain persons come to the hospital as private patients to the attending physician or surgeon, and that the usual fees are then charged. On the score of equity, there can be no possible objection to this. The physician or surgeon is entitled to his fee the same as if he treated the patient in a hotel. The advantages to both, however, are obvious in the increased facilities which are offered in a hospital for the treatment of disease, and especially when operations are required. But there are patients who frequently come into a hospital of their own accord, without any preference as to medical attendants, simply upon the general reputation of the institution, and the consequent guarantee which it gives for proper treatment. It is these cases who abuse the medical charity of the staff, and who assume that they have discharged all their obligations when their extra bed and extra board are paid for. Not only do these patients impose upon the staff, but upon the profession outside of the hospital. In this way the hospital, with perhaps the best of intentions, becomes indi-

rectly an abettor of fraud, and invites the commission of the very abuses which by its avowedly charitable mission it ostensibly aims to prevent.

How to remedy the evil is, as we have before intimated, somewhat of a problem. The hospitals are not likely to abolish the system of pay-patients, neither are the profession ready to say that with proper regulations the paying system in these institutions is not productive of great benefit. But where to draw the line, and how to do it, are not such easy matters to determine. We take the ground, to start with, that no patient able to pay for medical services should receive them for nothing, whether he be in a hospital or not. Every hospital physician and surgeon owes it to his profession to take a similar position.

It can scarcely be supposed that the managers of any hospital will insist upon a member of the staff rendering gratuitous services under such circumstances, but that they will be willing to listen to reasonable suggestions as regards a remedy. At first it might seem that a pay-patient entering the hospital without any special preference for a medical attendant, is under pecuniary obligation to the hospital alone for all the benefits he receives. Whether the hospital or attendant should receive the fee is a question between the managerial board and the staff. It would seem just, however, when the hospital receives pay for extra accommodations, that the staff should be compensated at ordinary rates for their services, which are really in the shape of extras to patients who can pay.

IMPURE WATER AND DISEASE.

THE sanitary effects of impure water, as originating epidemical diseases, appears to be one of those subjects which are forever coming up for discussion. The question, although obnoxious to many, must continually present itself, especially as the conviction is gaining ground, in the minds of some of our most eminent physicians, that the evils resulting from supplying cities with impure water will have to be radically met, and that without much delay.

It is much to be regretted that the connection between impure water and disease, although amply proved, does not rest on so exact an experimental basis as might be desired. In addition, it must be confessed that the evidence differs much, both in regard to the nature of the different diseases and the value of the testimony, which may arise from defective modes of analysis of water, or inability to make proper microscopical examinations, but probably the chief difficulty is caused by those coming in contact with such cases making but a superficial investigation.

If reference is made to the series of reports on the Public Health in England, by Mr. Simon, instances of outbreaks of enteric fever being caused by the excremental pollution of water, will be found by the

hundred; and while it is impossible to make even a rough estimate of the number of persons annually sacrificed by impure water, taking the cases of enteric fever alone, no less than 6,879 deaths occurred during 1877 in England and Wales, which were, as Mr. Ernest Hart says, intimately connected with filth, and thus wholly preventable. In the admirable fifth report of Mr. Simon, an abstract is given of no less than one hundred and sixty-four epidemics of typhoid fever, investigated by his department during four years, and in all these cases excremental pollution of air or water—generally both—was found. It will thus be seen that the careful and systematic investigations into the causes which have preceded a large number of epidemics in England, are gradually leading to a collection of facts and statistics which will be of the highest importance in arriving at a conclusion.

The recent outbreak of enteric fever at Caterham, England, which was traced, beyond a doubt, to the water-supply, is a striking case in point, although the nature of that supply appeared to preclude the possibility of its containing any impurities which could lead to such a result. In this case we are told by Dr. R. Thorne Thorne, F.R.C.P., who brought the matter before the National Health Society, that during the fortnight ending the 2d of February last, enteric fever broke out in the town of Caterham, and within a few hours at Redhill, an adjacent town, the total number of cases being 196 within the period named, the facts showing conclusively that they constituted an epidemic having a common origin. All the sanitary circumstances of the population were investigated, the systems of sewage and drainage, and the several means of excrement disposal. Every possible means of contagion was in turn dealt with, including the milk service. The water-supply appeared to be above suspicion; it was derived from chalk wells 500 feet deep, and had a decided reputation for being perfectly wholesome, and investigation showed that no contamination was possible by soakage from cess-pools or otherwise. But there was one fact which led to further inquiry in this direction, and it was this, that in the infected district the common supply of water was not used in 1,400 houses, the occupants of which used a private supply of water, and these people were all free from the epidemic which was raging around them. To be brief, for the case is given in the greatest detail, it was eventually found that a workman engaged in repairing one of the wells during the previous month suffered from a mild attack of enteric fever, accompanied by profuse diarrhœa, and was forced to evacuate in the adit, notwithstanding the regulations to the contrary, and within fourteen days the disease broke out in the form of an epidemic among the consumers of the company's water. As soon as these facts became known, the inhabitants were cautioned against the

use of the water, until all possible contamination was got rid of. The efforts in this direction were so successful that the epidemic soon ceased, and has not been renewed, although the water is again in general use.

It is not our purpose, in these remarks, to treat of the water-supply of this or other cities of the Union; but with this case officially before us, we cannot refrain from noticing, in passing, the notorious fact that the water-courses that supply the city of New York with its drinking-water are contaminated by very many sources of pollution, and that besides the general drainage of a district passing into the stream, Irish settlements, and dwellings of laborers upon the banks, have each their rough drain or sewer leading more or less directly to the lake. Bearing in mind that the district from which the croton supply of water is obtained, is always more or less troubled with fever, the public danger of the contaminations we refer to are too obvious to require further exposition.

We have briefly touched upon the various bearings of this important question, in the hope that by showing the deep interest exhibited by our professional confrères in England, in intelligently investigating the subject, that a like concern may be taken by our own physicians, whose opportunities for studying epidemical diseases are unfortunately greater than those presented to medical men in most civilized countries. It is this careful and patient collection of facts, and their thoughtful and scientific interpretation, that must place this question of water contamination in relation to the causation of disease beyond the pale of argument, and thus prepare the way for suitable preventive measures. We therefore repeat that our English brethren have shown us a good example.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

We are gratified to learn that the seventh annual meeting of this organization, to be held at Nashville, Tenn., on the 18th to 21st inst., bids fair to rival in point of interest and importance any of its previous gatherings. The circular issued August 15th, by the President, Prof. Cabell, and the additional announcement contained in the National Board of Health Bulletin, No. 14, evince a wise choice of subjects for discussion, which, if properly treated, will command public attention from all parts of the country. The subject of city sanitation, though considerably agitated by the public press, and studied by local health authorities, presents many points worthy of the careful consideration of a deliberative scientific body like the Public Health Association, while the "practical questions connected with the management of an actual or threatened outbreak of yellow fever" may be considered in these days of rapid communication, of great interest to the Northern and Western, as well as to the Southern States. We shall therefore at-

tentively watch the proceedings of this meeting, which cannot fail to be interesting and beneficial to the members and the general public.

No efforts are being spared on the part of those interested in the welfare of the Association, to insure the success of this annual meeting. Many of the railroads leading to Nashville offer reduced rates of fare; hotels extend to members and delegates liberal terms; and the local committee and citizens of Nashville are preparing to give the Association a cordial welcome.

Reviews and Notices of Books.

LECTURES ON SYPHILIS OF THE LARYNX, LESIONS OF THE SECONDARY AND INTERMEDIATE STAGES. By W. MACNEILL WHISTLER, M.D., M.R.C.P. London: J. & A. Churchill, 1879. Pp. 88.

THIS little book is a reprint, with slight additions, of two lectures delivered at the Hospital for Diseases of the Throat and Chest, London, and first published in the *Medical Times and Gazette*. The treatment of the subject, which does not touch upon the deeper lesions of the tertiary stage, is much more thorough than would be expected in a clinical lecture, and, in fact, has the completeness and detail of a monograph or of a chapter of a text-book. Its principal interest lies in the description of appearances found in laryngoscopic examination.

Reports of Societies.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, October 6, 1879.

DR. J. C. SHAW, PRESIDENT, IN THE CHAIR.

TUMOR OF CRUS AND PONS.

DR. R. W. AMIDON presented microscopic slides holding sections made from a tumor which involved the crus and pons. The point of interest centered in the question, "Are the nodules syphilitic or tubercular in character?"

RESOLUTION RELATING TO A CONSULTING BOARD FOR LUNATIC ASYLUMS.

DR. W. A. HAMMOND, under the head of Miscellaneous Business, introduced the following resolution, which was unanimously adopted by the Society.

"Resolved, That the recent board appointed by the Commissioners of Charities and Correction as Consulting Board to the Lunatic Asylums on Ward's Island and Blackwell's Island, though composed of distinguished physicians, does not represent the science of psychological medicine in this city, and therefore, in the opinion of this Society, is not competent to do the work assigned them."

Dr. Landon C. Gray, of Brooklyn, was elected Vice-President of the Society, to fill the vacancy caused by the resignation of Dr. Kiernan.

THE ASSOCIATION OF APHASIA WITH THE SYMPTOMS OF SO-CALLED SPASMODIC SPINAL PARALYSIS.

DR. GRAY read a brief paper, in which was related the history of two cases that illustrated the above

combination of symptoms. The association of aphasia is not infrequently observed in cases of cerebral hemorrhage, followed by secondary degeneration in the cord, but he was not aware that the same combination had been mentioned as occurring in any other class of cases.

Dr. E. C. SEOUTIN remarked that while he had seen a number of cases of infantile spastic paralysis, in none of them was there true aphasia. Speech was normal in all the cases except those in which there was an imperfection that was infantile, but was not aphasic; it was due to lack of development. He thought that, in the vast majority of cases, at least of congenital tetanoid paraplegia, there was no peculiar defect in speech which could be called aphasia. The motor tract was not necessarily intimately associated with the speech tract, and it was easy to conceive that a large number of cases of lack of development occurred with symptoms belonging to what was called tetanoid paraplegia, yet without impairment of the parts of the cortex or white substances which lie anterior to the common motor tract.

Dr. GRAY remarked that in his first case, more especially, the patient told him repeatedly that he could not recall words which he wished to speak, but that when they were pronounced for him he had no difficulty in repeating what was spoken to him.

Dr. HAMMOND stated that he had not seen *amnesic* aphasia associated with spastic paralysis, but within the last year he had seen two cases in which *ataxic* aphasia certainly was present. Memory was perfect, and there were no cerebral symptoms other than those relating to speech. In one of the cases the staccato speech was illustrated.

NERVOUS DISEASES IN EUROPE.

Dr. GEO. M. BEARD remarked briefly on the study of Nervous Diseases in Europe, and based his remarks on observations made during his recent visit there.

METALLOSCOPY.

While in Paris, Charcot gave him every opportunity to observe all his experiments, not only in the department of metalloscopy, but in trance, and the conclusions which he had reached from the observations then and there made are as follows:

1. Results far more interesting and informing, both in a physiological and in a therapeutical sense, have been obtained where the experiments were made in such a way as to make it absolutely certain that the only factor in producing the results was merely *subjective*—the mind of the patient acting upon the body. It is also established that, under any influence or mode of treatment calculated to act on the emotions in any way, it is difficult to exclude this subjective element of error which comes from the mind of the patient operated upon.

In his own experiments in mental therapeutics, thus far published only in abstract, Dr. Beard believed he had established the following:

By turning the mind of the patient on his body, through any process whatever, as by stating the precise hour when recovery will take place, by applying metals *outside* of the clothing, etc., it is possible to cure permanently as well as very rapidly, and in some cases instantaneously, cases of long-standing functional nervous disease.

Even *organic* structural disease may, in the same way, be relieved temporarily more speedily and satisfactorily than by any of our objective medication.

In any physiological or therapeutical experiments or measures, like the application of metals or magnets, or any very imposing proceedings that strike the emotions of ignorant or hysterical women, the presumption is, thousands to one, that the result, whatever that may be, is *subjective* and not objective, and this presumption must be overthrown before such experiments can be received as science.

2. On the other hand, the recent discoveries and inventions, of which the telephone, the phonograph, the audiometer are types and representatives, have proved that great results can come from changes in matter very minute and out of the range of the senses. It is also well known that a magnet can stop a watch, elongate an iron rod, and make music in it. These results so far are in favor of the claims of Burg, Charcot, and others in regard to metals, magnets, and solenoids.

3. The first presumption can be overcome only by a series of experiments on different patients, under different circumstances and at different times, in which all the six sources of error that apply to all the experiments with living human beings have been carefully eliminated. The six sources of error are the following: 1. Unconscious deception on the part of the subject experimented on; 2. Intentional deception on the part of the subject experimented on; 3. Intentional collusion of other parties; 4. Unintentional collusion of other parties; 5. Chances and coincidences; and, 6. Phenomena of involuntary life, the mind of the subject operating on the body and producing results. To eliminate these errors, the subject experimented on must be *deceived*.

4. The reports of experiments made by Burg and Charcot as they were *first* made, and the replies to criticisms upon them, contained no evidences whatever that these sources of error had been eliminated. It is right, and scientific, and necessary, therefore, that we should assume that the presumption that the results were subjective had not been overcome. Dr. Beard had nothing to recall or modify of his criticisms on these experiments in his pamphlet on that subject.

5. There is, however, *now* evidence of an important character that more recent experiments of Charcot and others have been made in such a way as to eliminate these sources of error; and if the statements of Charcot made to Dr. Beard are accepted, results have been obtained which, some of the time at least, are objective, and we have so far obtained an addition to physiological science. Similar results as those reported by Charcot in hysterical conditions have been obtained by Dr. McCull Anderson, of Glasgow, and, according to his own report, the elements of error were properly eliminated by the use of *false* magnets. When he used false magnets no effects followed; Charcot says the same.

6. The subject has therefore reached a stage where it may properly receive the attention of experts in this department. It is an open question waiting to be closed one way or the other. No experiments in this department are worth anything unless the subject is all the time deceived. The public exhibitions of Charcot prove nothing.

These questions, however settled, have a physiological more than a therapeutical interest. Charcot has abandoned metal therapeutics so-called, and regards his experiments merely as physiological curiosities. It is, however, not impossible that we shall find in these processes an addition of a certain value—perhaps a greater value than is now apparent, for relieving hysteria, neurasthenia, and allied states.

ELECTRICITY.

With regard to the use of electricity, not much progress had been made within the last few years. With regard to the question of direction of current, he was much interested to hear the views of Erb, who said that we did not know sufficient of the physiological action to tell what direction of current should be used therapeutically in the sense in which various writers were speaking upon that subject. Dr. Beard had long taught this doctrine, and thought it was the growing view upon that theme.

WATER IN THE TREATMENT OF NERVOUS DISEASES.

He also observed that water was more and more used in the treatment of nervous diseases. Charcot was using it a great deal, and sent many of his patients to an institution where they could get special treatment in that direction. As one means of counter-irritation, he was using a very fine stream of spray, sent against the skin with such force as to give a sensation of burning.

SEA-SICKNESS.

He experimented somewhat in the treatment of seasickness, and found that large doses of the bromides, sodium preferably, with caffeine, and hypodermics of sulphate of atropia, were effectual means for controlling the trouble. Bromides in 30, 60, or 90 grains daily, begun two or three days before sailing and continued while at sea, deprived sea-sickness of one-half of its terrors, and in that respect verified the claims made by Dr. F. D. Lente for the same remedy.

Sulphate of atropia hypodermics, $\frac{1}{100}$ of a grain, and repeated sufficient to produce dryness of the throat, gave very satisfactory results.

Caffein acted exceedingly well in many cases, given in two- or three-grain doses, and repeated in the same manner as when given for sick headache. Headache is the only symptom present in some cases of seasickness, and in those cases caffeine was especially serviceable.

HAY FEVER.

Dr. Beard also heard of three or four who had hay fever all the time they were on the ocean. One man was cured as soon as he landed in England.

The city of London, on account of its enormous size, was also a kind of refuge for hay fever subjects, a fact which he had not before known.

DR. HAMMOND said that the experiments performed by Charcot in the use of metals and magnets were such as were made more than one hundred years ago. While he did not dispute that the phenomena had been observed that was claimed by Charcot, he believed the same phenomena can be produced by the use of pieces of wood or tortoise-shell having the shape of magnets or metals. With reference to the delicate stream of water, he had used it for some twelve years, and regarded it as a very good form of counter-irritation, although he had not used it for some time.

DR. BEARD remarked that the only difference between his belief and Dr. Hammond's was that, if what Charcot told him was true, and if what McCall Anderson had published was true, he believed there was a possibility, based upon the statements of those two men, that the magnets *might* in some cases of hysteria produce a slight physiological effect. The fact that such phenomena could be in some cases obtained without using a real magnet, by mind acting on body, was nothing against some of the results claimed by Charcot.

The question was discussed at some length, after which the Society adjourned. §

Correspondence.

DETERMINATION OF SEX IN UTERO.

TO THE EDITOR OF THE MEDICAL RECORD,

SIR: In your issue of the 11th inst., Dr. T. C. Waite refers to a note of mine upon the subject named above, published in the RECORD of Nov. 23, 1878, which he must have read very carelessly, or he would not have ascribed to me experiments made in Switzerland and reported to the Agricultural Society of Canton de Vaud, in 1867. These experiments demonstrated the correctness of the Thury law for the production of sexes at will: namely, that conception following menstruation produces females, and conception preceding menstruation produces males. If Dr. Waite will again read my article he will see that I advanced no theory. It was not my purpose to do so. The truth or falsity of the Thury law can be sooner and more satisfactorily demonstrated by careful experiment than by the evolution of theories which must remain, more or less, the subject of controversy. If the law be correct, or even if extended experiments prove that only a majority of cases follow the rule, the fact ought to be known. Every practising physician will meet with instances where this knowledge would confer untold happiness. The variable periods of gestation and the difficulty of determining the exact time of conception, tend greatly to hinder research in this field; but if every accoucheur would diligently inquire into the matter, much valuable information would be elicited. If it be found that where the full-term delivery occurred at or before the expected time, the child is female, and where gestation goes on longer than was expected, the child is male, the evidence will be strong (but not conclusive, I admit) in favor of the proposition of Prof. Thury. Again, there are but few physicians who have not had an opportunity among their patients, whose judgment and candor he can rely upon, of fixing exactly the time of conception. It was to call attention to these observations—to promote interest that would lead to extended experiment, and not to elaborate any theory, that prompted me to write the short article of one year ago. I may say that my investigations since that time point without exception to the same conclusions.

I might well refer Dr. Waite's question, which he thinks will knock the theories of the "learned doctors" into "infinitesimal atoms," to others than myself who have written upon the subject, as I have not advanced any theory and cannot presume to class myself among the "learned doctors." But as I am the only person he names, I will say that a plural pregnancy of different sexes argues nothing against the correctness of the Thury law. It could only do so if it were a fact that every plural pregnancy is the result of a single act of insemination, by which the two or more yolks which are occasionally found in one ovum are simultaneously fertilized. But such is not the case. More than one ovum may be contained in one Graafian vesicle, or more than one Graafian vesicle may be expelled from one or both ovaries, and these may be fertilized by a single act, or by different acts, of insemination. That the last proposition may be true is proved by cases on record where white women have borne twins, one white and the other mulatto. Will Dr. Waite undertake to assert positively that twin pregnancies of different sexes are NOT the result

of separate acts of insemination, the male the product of that previous to, and the female of that after menstruation?

Respectfully,

JOSEPH A. MUDD, M.D.

NEW SALEM, Mo., Oct. 21, 1879.

DETECTION OF STONE IN THE BLADDER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I notice in your August 2d Journal a note on detection of stone in the bladder by means of iron wire bent to touch the ears and connected with the sound. If the author of this method, or any one disposed to try it, will attach a wire to his sound and take the unattached end of the wire *between his teeth*, he will find it will betray minute touches with surprising delicacy.

Respectfully,

JAMES B. HODGKIN.

WASHINGTON, D. C., Oct. 21, 1879.

THE PROLONGED RETENTION OF LIFE IN THE NEW-BORN.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Recently I received a call from a lady living at some considerable distance from my office, and knowing naught of the case, indulged in no particular haste to answer. It proved to be an obstetrical one, and upon my arrival, a lady, the only person present with the patient, stated that the child had been born over half an hour, and was dead; she was positive about the time, and referred to a clock in plain view on the mantel. Since its birth she had proceeded to a physician over half a mile distant, only to find him absent. The labor had been precipitate, and I found the child lying between the mother's thighs, the head being pressed firmly against the vulva, and held there by the cord which passed about the child's abdomen, and then took two turns about its neck, while the placenta was still held securely in utero. The turns about the neck formed a sort of clove hitch, and were so tight that my finger could not be inserted beneath until the cord was severed. Notwithstanding the cessation of pulsation and deep cyanosis, the results of at least thirty minutes' complete strangulation, yet persevering and long-continued efforts at resuscitation were successful. Every accoucheur sees such, and even graver instances, illustrating the almost incredible prolonged retention of life in the new-born who have not breathed, and this remarkable power to resist the deprivation of air actually remains in a decreasing degree even to the fourth and fifth day of life. The experiments of Legallois show that puppies and kittens may be kept under water immediately after birth, with impunity, for a period not less than twenty-eight minutes. In some experiments carried on by myself, it was found that puppies two days old died only after being submerged from fifteen to nineteen minutes, while one of the same age, who showed no effects after one hour, from the subcutaneous injection of morphia, gr. ss., being then submerged, succumbed in seven minutes. The human still born fetus can live longer without respiration than can any other mammalian fetus.

The cases in the "Gazette Hebdomadaire" for December 1, 1824, fully demonstrate this fact.

The following cases can be found in Braithwaite's Retrospect, Part XXXI.

A woman, *æt.* 25, who had tried to conceal her pregnancy, was delivered w enscated on a tub. The infant, born without any signs of life, was buried in a sand-pit, and, after remaining there for half an hour, was removed, and lived.

In 1850 a young woman was tried by the tribunals of Berlin, who had buried her new-born male infant, believing it to be dead. After an hour the infant was disinterred, and recalled to life.

T. P., a servant, *æt.* 23, was delivered in a stable, when leaning against the wall, alone, and in a state of unconsciousness, about half past four A.M. When she came to herself, she found the infant on the ground, having a spade lying upon it, with its cutting edge turned to the body. She took the infant, which was perfectly cold, believing it to be dead, and with the placenta attached, wrapped it up in her apron and buried it in the garden. Suspicions arose that she had been confined; she confessed, and at half-past nine the infant was dug up from a depth of thirty centimetres. It was found lying on its face, with the placenta under the abdomen. Though cold, apparently dead, and pulseless, the cord was tied. For two hours, P., a surgeon, used means to reanimate it; when at last it began to breathe freely, gradual signs of life became more evident, and it cried. Some slight wounds were observed on its body; wounds in the neck which did not bleed at first, bled when the infant was restored. On the 17th and 18th the wounds suppurated, and on the 19th it died of convulsions. The physicians intrusted with the judicial autopsy reported that it had been inhaled before it breathed, and that it had not breathed till after it was exhumed.

From the above one would seem to be encouraged to persist much longer in the attempts at resuscitation in cases of infantile asphyxia than is generally done by the majority of us, and he who would be the most successful in such attempts need not be the most skilful, but must be the most patient and persevering.

Respectfully,

A. C. HOFFMAN, M.D.

JERSEY CITY.

LITHOTRITY BY THE SURGICAL ENGINE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—That lithotripsy is still in its infancy, and will ultimately do away with the dangerous operation of lithotomy, I have not the least doubt. I have paid much attention to this subject, but never saw my way clear to any practical operation to effect this great desideratum, until the introduction of the surgical engine. In making suggestions in regard to the improvements of the present mode of lithotripsy, let us make an inquiry into its main objection. This appears to be the local and constitutional effects of the use of the lithotrite. It is a matter of importance to ascertain the seat of irritation caused by the use of the instrument. It is evidently within the channel of the urethra, and near its entrance into the bladder. The anterior urethra will tolerate a short bougie without any of this characteristic irritation, which I have repeatedly tested by a system of treating gleet with atmospheric pressure with short bougies (*vide* "Medico-Chir. Review," Phila.); and, on the other hand, the bladder is accustomed to a foreign material, and besides, is not subject to any special hyperæsthesia, except at the neck of the bladder, where it impinges upon the internal opening of the urethra.

The clumsy introduction of a catheter into the blad-

der will induce this same irritation and its consequences, but one introduced with care and skill, and left within the urethra even for hours, may cause little or no trouble. It is not the presence of a polished foreign body at this seat of hyperaesthesia, but the friction of its use that produces the mischief.

To make lithotripsy uniformly safe and successful, we have to construct and use such instruments as will meet this difficulty. To bring about these favorable conditions, first introduce any easy bougie into the bladder, and allow it to remain for a short time. Continue this operation daily, only increase the size of the bougie, and extend the time of its retention as you pursue the treatment. By this procedure you effect two things—you establish a tolerance of the instrument, and at the same time effect a dilatation of the urethra. For the final operation, introduce into the bladder a silver catheter of the size of the last bougie that was used. The catheter is to be made of a very thin sheet of silver; and the bladder-end of it, so shaped as to facilitate its introduction, is fixed to the style, which is removed after its introduction into the bladder. This catheter gives us free access into the bladder—to wash out its contents—and for the repeated and ready introduction of instruments, without inflicting the least violence of the soft parts.

The lithotrite to be used is made light and elastic in the stem, so that it can be readily introduced through the catheter, with a clasp to hold the stone pretty much after the usual style. The instrument is made of the best steel, and in fashion for its ready passage, in particular through the curve of the catheter. It is an instrument simply to hold the stone, and not to crush it.

After the stone is secured by this instrument a drill is passed through it, terminating within its clasp. This drill is fastened to the end of a steel wire, and in order to insure protection to the soft parts of the interior of the bladder, its action must be strictly limited within the jaws or clasps of the lithotrite. After the stone is secured with the lithotrite, the drill is introduced and brought to act upon the stone by the surgical engine. A revolution of two thousand per minute will soon drill a hole through it. After one hole is thus drilled, change the position of the stone and drill another, and so on until you have demolished it. The instrument can be removed repeatedly, either to wash out the bladder, to inject water, or to extract fragments of the stone, without causing the least irritation to the urethra that is so well protected by the silver catheter.

There will be no difficulty in getting rid of the debris of the stone if the instruments are properly constructed, for by water and the contraction of the bladder we ought to be able to get rid of every particle of the stone. By this method of operating, the stone can be removed at one sitting with little or no pain or constitutional troubles as a consequence.

GEO. P. HACHENBERG, M.D.

AUSTIN, TEXAS.

SOME REMARKS ON CLIMATOLOGY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The following letter is from a very intelligent gentleman, an invalid, who has travelled very extensively over the world, and who has lately made climatology a study, and is now engaged on a work descriptive of the health resorts of the old and the new world. Although the letter is a private one, and not at all intended for the public eye, I think it may prove interesting just now to some of your readers

who are being consulted about a suitable climate for the coming winter.

Yours truly,

FREDERICK D. LENTE.

MILAN, October 3, 1879.

My Dear Doctor:—I am studying the European health resorts at present, and with all the impartiality of which I am capable. Florida holds the first rank, and I place it above Egypt and Algiers also. Almost all the European winter resorts are irritating in their influence on the nervous system. The Riviera resorts are especially so; invalids, as a rule, find great difficulty in sleeping. Such exciting climatic influences, I take it, must be disadvantageous. You accentuate, and I think none too strongly, the necessity for plenty of pure air in consumption.

Taking this view, there is not one known resort on the Riviera that should not now be tabooed to that class of invalids. Cannes, Nice, Monaco, Mentone, San Remo, and even Hyères, have grown into large towns, crowded on one side by the sea, and on the other by mountains. The mild climate of this coast is principally owing to the protection from wind it enjoys. With the exception of an occasional "mistral," the air changes very little. The sea is tideless, and the drainage of what is now almost a continuous town is poured into this currentless water. The drainage of the hotels is also bad beyond belief, and, as a consequence, typhoid and all sorts of low fevers are prevalent.

Ten years have made a great change in the Riviera. When I first knew it, the conditions of health were better. Egypt is not an irritating climate to the nerves, but is so to the mucous membranes, especially to the stomach. About February, however, commence what are called the "khamsen" winds, which are intensely hot, dry, and exciting winds. They prevail from February to June, and last usually two or three days whenever they blow. The ordinary day temperature at that season in Cairo, say 60° to 70°, and night temperature, say 34° to 50°, is changed by these winds in a few hours and raised to a continuous heat of from 95° to 120°. The latter temperature I myself recorded last May, seventeen miles from Cairo, at a sulphur spring called "Helonan." The temperature falls as rapidly as it rises. I knew of several serious cases of hemorrhage from the lungs during these winds. As they commence too early for invalids to risk safely a voyage on the Mediterranean, they seriously impair the usefulness of Egypt as a health resort.

Hoping to hear from you again,

I am yours sincerely,

ABBOT KINNEY.

FLEXIBLE VULCANITE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—As material for pessaries India rubber is liable to the very great objection that it becomes fetid and macerated in the vaginal fluids, exciting leucorrhœa and erosions. Vulcanite is free from these difficulties, but it is rigid, inelastic, and therefore splints the vagina, and tends to atrophy of its muscular elements. The hard rubber or vulcanite instruments often become imbedded in the tissues, and produce œdema and ulceration. In the attempt to combine the advantages and to eliminate the disadvantages of these materials, I have produced a new instrument, which is now offered to the profession for trial. It has a coil of fine wires braided into a cord and covered with a modified vulcanite, which, while it retains the finely

polished and hard surface of ordinary vulcanite, is still flexible and elastic.

The instrument may be bent, without the aid of heat, by the *fingers only*, and will *retain* the shape thus given to it. It is for this combination of materials only that originality is claimed.

Several have been worn by my private patients from one to three months, and are found to retain their fine surface unaltered, and have not been found to produce the inconveniences of soft rubber. The instrument is cheaper than many, and may be found at Schmidt's surgical instrument store, on Broadway and Thirty-fourth Street.

W. M. CHAMBERLAIN.

58 WEST FORTIETH STREET, Sept. 30, 1870.

SOME CASES OF BRIGHT'S DISEASE TREATED WITH JABORANDI.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—As the brief records of some cases of Bright's disease in which jaborandi was employed may be of interest, permit me to submit them.

CASE I.—I was called one evening to see a woman said to be hysterical. I found, indeed, all the symptoms that are given by the best authors of that protean malady; but, as the patient was pregnant, and had some headache, I endeavored to procure some of her water. It was impossible to get more than a drachm, as she fought like a tigress. It contained some albumen. I ordered free purgation, and gave bromide of potash, chloral, tr. valerian to quiet her. Eight hours after, I was again called to see my hysterical patient in "fits." Os uterus slightly dilated, and her convulsions occurring at each contraction of the uterus. I sent for forceps, and dilated the os uteri rapidly. I gave hypodermically $\frac{1}{4}$ gr. of pilocarpine. It acted promptly, and her convulsions were so modified that I gave her, in a half-hour, another injection of the same amount. The child was now delivered. Some other convulsions occurred after the birth of the child. Again I resorted to jaborandi, and again I succeeded. The purgation was thorough. The woman recovered.

CASE II.—I was called shortly after to see a woman in puerperal convulsions. Two physicians had seen her, but one said to administer chloroform and she would come all "right," and the other refused to attend. The patient's convulsions were terrible, one every three minutes. The os was only partially dilated. Chloroform did not yield me very good results, so I resorted to jaborandi. Her skin was dry and hot. I threw up thirty minims of the fluid ext. of jaborandi per rectum. The œdema of the lungs which followed was so awful that I hope I may never see such again. I gave her up as lost; and, as the fatal heart had ceased, I determined to wait her death before delivering. To my surprise, after an hour of these terrible symptoms, and by the free injection of ammon. carb., my patient rallied, and became conscious for the first time in twenty-four hours. I sent for my father, Dr. John Burke, and she was delivered. Everything appeared well. She had lost much blood, but she appeared to be doing nicely. I left. Was called back in two hours. She had another convulsion. I gave $\frac{1}{2}$ grain of pilocarpine, and, although it stopped the convulsion and did not occasion much œdema, she sunk and died some hours after, spite of my most strenuous exertions.

CASE III. was a young man who, after being purged freely and cupped, still complained of head-

ache, and had, with a dry, harsh skin, all the initiatory symptoms of a convulsion. The hypodermic injection of $\frac{1}{4}$ of a grain of pilocarpine and an equal amount of Magendie's sol. of morphia, by the orders of my father, Dr. John Burke, produced a most profuse perspiration and an agreeable sleep, which lasted for six hours, after which all his symptoms disappeared, and, with the rational continuance of appropriate medication, he recovered.

MARTIN BURKE.

117 LEXINGTON AVENUE.

New Instruments.

NEW ARTERY AND TORSION FORCEPS.

By C. S. WHEELER, M.D.,

BRAITLEBORO, VT.

BELIEVING that the best results in surgical practice are due in some measure to the use of proper instruments, the author has devised this new forceps for the purpose of ligation or torsion of divided vessels, chiefly, however, to encourage the latter operation. It is needless to remark upon the advantage of checking hemorrhage without leaving a foreign substance—as a ligature—in the wound. That ligation of the larger arteries is the proper treatment, we believe; but that the smaller arteries may just as properly be twisted is an established fact.

The instrument illustrated is a combination which, we believe, all surgeons will appreciate. It consists of two pair of blades, the smaller, intended for torsion, revolving freely within the larger fenestrated pair; and when open, as shown in the cut, the inner pair is so arranged as to rest in a groove and follow closely the outer pair, so that when closed upon the artery the vessel is held by both pair. A ligature may then be applied, as with the ordinary fenestrated forceps; or, in case torsion is desired, the inside pair may be fastened by its slide-catch, the outer pair unlocked and the artery drawn out, held by the inside pair by the button at the base of the instrument; the outer pair is again closed on the vessel, holding it firmly while it is twisted by rotating the inside pair by turning the button at the base.

In case of emergency the button may be unscrewed and the inner forceps withdrawn, to serve the purpose of a small mouse-toothed forceps.

The instrument is manufactured by Messrs. Tiemann & Co., of New York City.

THE CRAVINGS FOR ALCOHOL.—The most reliable temporary relief for the cravings of alcohol, according to Dr. Kerr, is furnished by a full emetic dose of ipecac. Dr. Kerr is the advocate for red cinchona in the treatment of dipsomania.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Oct. 26th to Nov. 1, 1879.

IRWIN, B. J. D., Major and Surgeon. Having reported for duty at these headquarters, he is assigned to duty at Fort Meade, D. T. S. O. 116, Dept. of Dakota, Oct. 21, 1879.

GIBSON, J. R., Major and Surgeon. Having reported at these headquarters, to proceed to Fort McIntary, Md., and report to the commanding officer for duty. S. O. 192, Dept. of the East, Oct. 28, 1879.

TREMAINE, W. S., Capt. and Asst. Surgeon, Fort Dodge, Kansas. Granted leave of absence for one month, on surgeon's certificate of disability, with permission to leave the dept. and apply for two months' extension. S. O. 214, Dept. of the Missouri, Oct. 27, 1879.

HALL, J. D., Capt. and Asst. Surgeon, Fort Concho, Texas. Granted leave of absence for one month, on account of sickness. S. O. 221, Dept. of Texas, Oct. 20, 1879.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 1, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebrospinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Oct. 25, 1879. . .	0	19	34	1	36	33	0	0
Nov. 1, 1879. . .	0	13	41	1	66	32	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from October 28th to November 4th, inclusive, was 5, and the number of deaths that occurred was 2. The total number of cases for this year to November 4th is 1,538, and the total number of deaths, 552.

No new cases have been reported since October 30th.

CHOLECYSTOTOMY.—The distinguished surgeon, Lawson Tait, of Birmingham, writes to Dr. Marion Sims: "You will be pleased to learn that I did a cholecystotomy on an unadherent distended gall-bladder, towards the end of August, and that the patient is now perfectly well. I removed one stone entire, but had to crush the other, it was so firmly impacted in, and adherent to, the orifice of the gall-bladder. I read the case before the Medico-Chirurgical Society of London."

THE LATE DR. EUGENE PEUGNET, OF FORDHAM, N. Y.—At a special meeting of the Yonkers Medical Association, held October 12, 1879, the following minute was adopted; a copy was ordered to be sent to the family of the deceased, and to be published in the medical papers:

"The Yonkers Medical Association desire to express their deep sense of the loss they have suffered in the death of Eugene Peugnet, M.D., of Fordham, N. Y., a member of the Association, who has so suddenly been taken from our midst, and to put upon record

also their appreciation of his character as a man, and of his marked professional attainments. He was ever a regular and faithful attendant upon the meetings of the Society, and was always ready to do his part, contributing largely to their scientific interest. By his eminent ability and peculiar qualification as a surgeon, he gave to the meetings a superior tone and dignity. He exhibited a rare example of one whose interest and aim were directed towards elevating the character of the profession which he so dearly loved. We desire as a body to offer to those whose home his death has made desolate, our sincerest sympathy, and to make our prayer that He who has visited them with trouble, would look with pity upon their sorrows, would remember them in mercy, and comfort them with a sense of His goodness, lifting up His countenance upon them and giving them peace.

R. A. JOYCE, M.D.,
ARCH. M. CAMPBELL, M.D.,
F. S. GRANT, M.D.,

Committee."

ENGLISH PHYSICIANS IN CANADA.—The English law allows persons registered as physicians or surgeons in England to practise in Canada with no other formality than that of registering themselves. A petition was presented last summer by the College of Physicians and Surgeons in Ontario begging that this might be done away with, and that English medical men might be obliged to submit to an examination for license. It was claimed that the law infringed on the rights of self-government conferred on the Provinces, and also that a person who had been only registered as a physician or surgeon in England might come to Canada and practise both branches.

The petition seemed to be framed more especially in the interest of the Canadian medical schools, and it has not been granted by the Home Government.

THE CROSSING OF SPECIES.—Dr. Vandell, in his letter from Paris to the *Louisville Medical News*, describes his visit to the Jardin d'Acclimatization. He was shown there a fertile mule which had borne half a dozen colts, some of them by zebras, some by an ass, and some by a stallion. There were also many crosses produced between the zebra and ass, the horse and zebra, etc. The fecund mule, however, was considered the greatest rarity.

RUSH MEDICAL COLLEGE, CHICAGO.—The Rush Medical College commences its winter session with four hundred students. Considering the number, the institution seems to be appropriately named.

THE LOWEST FORMS OF LIFE.—At a recent meeting of the Philadelphia Academy of Natural Sciences, Dr. Leidy referred to the structure of the low forms of infusorial life known as the amœba, upon a study of which and allied creatures he had been engaged for some time past. (A large and profusely illustrated work on "The Lower Forms of Life," from the pen of Dr. Leidy, is to be published at an early date in connection with the last Hayden survey.) He said that the species of the true genus amœba all possess a nucleus and a contractile vesicle. He believed that the latter organ, if it may be so called, performed the function of a combined heart and lung, as currents of liquid were probably received and expelled by it. It would be remembered that a form of life still lower than the amœba, inasmuch as it is devoid of a nucleus, had been described by Hæckel under the name of protamœba. Recently, Professor Butschli had described an interesting species which he had found parasitic in the intestinal canal of the common cock-

roach. Dr. Leidy was glad to be able to confirm all of Butschli's statements concerning this curious little creature, which he had observed in the situation indicated. He believed, however, that it should be placed in a genus distinct from the amœba, as it possessed permanent characters, which placed it between that genus and the protamœba. A distinct nucleus and nucleolus can be readily seen, but no trace of a contractile vesicle has, as yet, been discovered in it. In the typical amœba the protoplasm of which the animal is composed divides itself into two portions—a clear outer film and granular contents. In the new form no such division of substance can be seen during life, although the two portions separate after death.

These characters seemed sufficient to distinguish the creatures generically from those heretofore described, and Dr. Leidy therefore proposed for it the name of *eudomœba*, retaining the specific name *blattæ* proposed by Butschli. This rhizopod is of interest to the student of microscopic life, because of the ease with which it can always be obtained for examination, and because it forms probably the simplest and yet the most complete example of a living organic cell—a particle of protoplasm containing a nucleus and nucleolus, and nothing else.

In answer to a question of Prof. Koenig, Dr. Leidy stated that it was commonly believed by those who studied infusorial life, that all the forms containing chlorophyll gave off oxygen after the manner of plants. The belief was not founded merely upon the green color of the contents, but upon experiment. He did not think that this liberation of oxygen by animal matter was necessarily contrary to the logic of nature, because we have not been able to positively distinguish animal from vegetable life.

THE MEDIA, PA., TRAINING SCHOOL FOR CHILDREN.

—The annual meeting of the contributors to the Pennsylvania Training School for Feeble-minded Children, was held recently near Media. The Hon. Edward A. Price presided. Dr. Alfred L. Elwyn, President, read his annual report, which urged the necessity of erecting a new asylum building, in connection with the institution, for what are called "custodial cases," by which poor children severely afflicted should receive not only shelter and care, but such development as their condition will admit of. The report, in urging the necessity for the erection of such a building, embodied an application for aid from the State.

Dr. Isaac N. Kerlin, Superintendent, read his annual report, which, speaking of the subject presented in the President's appeal, reiterated the demand for such increased facilities, and sketched a proposed plan of the organization, system of management, general workings, and the cost for an asylum building.

Allusion was made to certain events occurring during the year, among which were the following: The National Association of Officers of Institutions for the Feeble-minded, inaugurated at Media in 1878, held its Second Annual Session at the Illinois State Institution in May last, and was attended by Dr. Kerlin. The session was productive of much benefit to the general work. On the 23d of May last, the State Medical Society of Pennsylvania paid a visit to the school, and general satisfaction was expressed with the character and workings of the institution.

The improvements made during the past year embraced the erection of a three-story shop building of brick, measuring twenty by eighty feet, at a point safely distant from the main building. This is now used for mattress- and broom-making, and is well

suitable to the requirements of any trades and occupations such as may be hereafter added. Other alterations are now being made for the improvement of the size and condition of the house.

Appended to the Report was a series of tabulated statements, giving the following showing of the condition of the institution: The number of children remaining in the home on September 30, 1879, was 316, 201 of whom were boys. The support of these inmates was as follows: Wholly supported by the State, 162, partially, 8; Soldiers' Orphan Fund, 2; by the city of Philadelphia, 16; by the State of New Jersey, 49; by Delaware, 1; by the free fund, 6; by parents or guardians, 55; and by the institution, 17. During the year 60 children were admitted, of whom 43 were males. The number discharged during the same period was 32—viz., 23 males and 9 females.

The treatment and condition of the children was thus described: Improving under training and treatment, 162 boys and 71 girls; stationary, 20 boys and 26 girls; deteriorating through age or disease, 19 boys and 18 girls.

The inmates of the house were thus classified: In school and training department, 99 boys and 55 girls; in the manual labor department, 64 boys and 40 girls; and in the custodial department, 38 boys and 20 girls.

The report was adopted as read, and the following officers were elected:

Patron.—His Excellency, Hon. Henry M. Hoyt, Governor of Pennsylvania.

President.—Alfred L. Elwyn, M.D.

Vice-Presidents.—One year: H. B. Tatham, Samuel A. Crozier; two years: MacGregor J. Mitcheson, Wistar Morris; three years: Geo. Martin, M.D., John M. Ogden.

Directors.—One year: Wm. F. Miskey, Isaac Jones, Chalkley Harvey, Edward A. Price; two years: Jas. A. McCrea, M.D., Joseph R. Rhoads, Evans Rogers, Samuel Bancroft; three years: Geo. Bailey, M.D., Wm. H. Miller, Isaac Worrall, Amos Bonsall.

Treasurer.—Joseph K. Wheeler.

Secretary.—Franklin Taylor.

Superintendent.—Isaac N. Kerlin, M.D.

SPONTANEOUS CURE OF INVOLUTION OF UTERUS—Dr. W. H. Mather, of Sutfield, Conn., writes: "Mrs. Eliza — had a miscarriage in December, 1868; flowed until March 15th following, during all of which time was without medical attendance. Was regular then until September 25th, 1879; flowed ten days. I was called and found the patient sitting, but bloodless and unable to walk. On examination, found the womb involuted to such an extent that the top protruded through the os. I failed to return it with means at hand; gave her opiates, and ordered rest. Saw her again the third day, and what I had failed to do nature had done, and restored the organ. The patient believed she retained a portion of the afterbirth from December until September, when she had violent pains and excessive flowing, with the discharge of a fleshy mass which she believed to be a portion of the placenta. I believe the uterus was involuted during ten days."

THE NEW YORK THERAPEUTICAL SOCIETY.—At an annual meeting, held October 17, 1879, the following officers were elected for the ensuing year: Dr. A. Jacobi, President; Dr. Robert F. Weir, First Vice-President; Dr. Mary Putnam-Jacobi, Second Vice-President; Dr. Andrew H. Smith, Recording Secretary; Dr. E. C. Squin, Corresponding Secretary and Treasurer; and Drs. V. P. Gibney and H. T. Hanks, Members of the Council.

FOREIGN QUININE—It is stated that some of this quinine, offered as pure, contains twenty per cent. of cinchonidia in it. As a great deal of foreign quinine is being put upon the market now, physicians can bear the fact in mind. Cinchonidia is the least powerful of the four alkaloids.

A CASE OF POISONING BY CHLORATE OF POTASSIUM.—J. K. Boude, M.D., of Carthage, Ill., writes: "A healthy, robust girl, aged two years and eight months, gained access to a bottle of chlorate of potassium, and ate about three drachms of the crystals. As she had partaken of food a short time previously, and drank largely of water immediately afterwards, no symptoms of poisoning showed themselves for two hours, except that she complained of a pain in her stomach about half an hour afterward, which was supposed to arise from indigestion, and was treated with paregoric.

Two hours after she had ingested the drug, she vomited very freely, ejecting from her stomach the food and water that she had taken. She passed from her bowels at the same time a large quantity of greenish mucus, followed by a clear mucus. After this she became much prostrated, with a feeble pulse and a bluish, ashen hue of countenance. It was not discovered until this occurred that she had taken so much of the drug; and a physician was then called in.

Under the use of alcoholic stimulants the prostration soon passed off, and she commenced playing, and continued to do so for more than two hours; but she seemed to be in a state of excitement, and played boisterously.

She then slept for two hours, and on waking, asked for water and ate some. She seemed very restless, and her countenance still had the bluish appearance.

At 8 p.m., eight hours after she had taken the drug, she vomited again, and became very much prostrated, and was thought to be dying; but she again rallied under the use of stimulants. The matter ejected was simply the water and food she had taken. She slept tolerably quietly until midnight, asking for water frequently; at that hour her bowels moved again, the passage being greenish water and slime, after which her extremities became cold, and the pulse became imperceptible at the wrists. Stimulants were freely administered, but without effect. At 2.30 a.m. she vomited a large quantity of water, after which she sank very rapidly, and died quietly at 2.45 a.m., just fifteen hours after she had taken the drug.

"She complained but once of pain in the stomach and bowels, although frequently asked. During the first part of the night her heart beat with great force, so as to jar the hand when placed over the precordial region, and her pulse was full and bounding. The urinary secretion was increased during the afternoon, and seemed irritant to the bladder; and there was no suppression nor abnormal appearance of the urinary secretion."

THE SICKNESS-RATE IN WISCONSIN.—The proportion of sickness to death in Wisconsin, as given by the State Board of Health, is fifteen to one. The rate usually given for a population is twenty-seven to one. Either the returns are incomplete, or the Wisconsin doctors treat their patients very vigorously.

PROF. VIRCHOW has become a member of the Society of Americanists, an archaeological association which devotes itself to studying the pre-Columbian history of the American continent.

ALCOHOL IN BRAIN TISSUE.—According to Dr. Maurice Perrin, the brain of a dog killed while com-

pletely intoxicated contains two per cent. of alcohol. Dr. Perrin does not state that the same proportion exists in man. Applying the figures given, however, it might be inferred that one-tenth of the alcohol that a man drinks unites with his cerebral tissues.

CLAUDE BERNARD'S TREATISE ON ANATOMY.—This much-talked of work has been curiously disposed of. The privilege of publishing it in the future was sold at auction in the office of a Paris notary on the sixth of October. The starting price was twenty thousand francs for the letter-press and five thousand francs for the illustrations.

MEDICAL WOMEN.—Dr. Rosa Well, a young lady from Vienna, has been appointed by the Faculty of the University of Bern, assistant lecturer to Professor Pfüger in the branch of ophthalmology. Woman has been said before to have made a specialty of the eyes, and her labors are now receiving a scientific recognition.

RABIES.—Canine rabies can be transmitted to the rabbit; and M. Gattier, of Paris, has taken advantage of this fact to study the effects of antidotes to the poison. None have been as yet found. The possibility of inoculating the poison in the rabbit, however, affords a convenient way of testing the question as to whether a dog is rabid or not.

LARYNGEAL PHTHISIS.—At the last meeting of the British Medical Association, Dr. Morell McKenzie read a paper on this subject, which showed that either our English brethren are much behind us in the knowledge of this affection, or the disease has a different course in New York. His conclusions were: (1) that laryngeal phthisis was due to the presence and subsequent breaking down of tubercles in the mucous and submucous membranes; (2) that laryngeal phthisis is essentially a secondary phenomenon, and always occurs as a sequel to pulmonary phthisis; (3) that the prognosis is always unfavorable, the ordinary duration of life after the throat symptoms have become troublesome being from twelve to eighteen months.

None of these conclusions, we believe, are accepted in toto by the best American laryngologists.

RECTAL HEMORRHAGE IN INFANCY.—Dr. A. W. Bell, of Moodus, Conn., writes: "In a recent number of the RECORD I notice an article from Dr. Manley, of Lawrence, Mass., on 'Rectal Hemorrhage in Infancy.' I was reminded, by reading it, of two similar cases of my own. On September 23, 1875, I attended Mrs. D— in her first pregnancy. On the day following the confinement, the child vomited blood and passed the same per anum. I made no record of the case at the time, and do not now remember the treatment; however, the child died on the morning of the 25th. At the post-mortem, a spot in the stomach was found near the pylorus, from which we supposed the blood to have originated. The day previous to the one on which the mother was taken in labor, she fell backward from a chair on which she was standing, and sat down on a door-sill. That night she was taken with pain, which continued for forty-eight hours without uterine contraction, and which resisted all measures used for its relief. At the end of this time the uterus contracted, and the child was delivered within twelve hours.

The second case I was called to see when the child was three days old, on October 25, 1878. In this case there was no vomiting of blood. I prescribed gallic acid internally, but the child lived only two hours after. There was no post-mortem."

VIRCHOW AS A MAGICIAN.—Prof. Virchow, while engaged with Dr. Schliemann in making excavations

at Hissarlik, Asia Minor, found several of the workmen suffering from an obstinate fever. He took them in charge and cured them. His reputation as a magician was at once established, and in a short time the sick from all the country round flocked to him, so that he had a clinic each morning in front of the wooden shanty where he slept. Before leaving he had dug a deep hole, into which he descended every day with a candle for purposes of exploration. All his movements were watched by the admiring crowds. When he went away the hole became filled with water, and now it is called by the people "Virchow's Well." Every day the sick are brought to it, and drink or wash in the healing fluid. A whole country consider Virchow the greatest magician that ever lived.

THE ENGLISH NAVAL MEDICAL SERVICE.—At a recent competitive examination of candidates for medical commissions in the Royal Navy, ten candidates presented themselves. Three were declared physically unfit; all the rest passed the examination. This presents a marked contrast with the naval examinations in this country, to which there are often thirty or forty applicants for two or three vacancies.

ASSOCIATION OF GERMAN NATURALISTS AND PHYSICIANS.—This association held its annual meeting at Baden-Baden, during the week from Sept. 18th to Sept. 24th. The work was done in twenty-three sections. Among the prominent medical contributors were Profs. Jürgensen, Benedikt, Erb, Lücke, and Eulenberg.

MEDICINE IN LOUISVILLE.—There are in Louisville, according to the *Medical News*, five medical journals and four medical colleges; and we are informed that there are still from ten to twenty members of the profession who haven't a professorship. Two of the colleges which claimed to be separate, but occupied the same building and were run by one faculty, have now openly separated and have each its own building and professors.

CHOLERA IN INDIA.—There is a severe epidemic of cholera in British Burmah.

PILOCARPINE IN ECLAMPSIA.—Dr. Bidder reported in the *Vienna Medico-Chirurgical Review* of October, 1878, two cases of puerperal eclampsia cured by the use of pilocarpine. The attacks occurred both before and after delivery. The remedy was given in doses of about three grains; chloral was given at the same time, however.

FRENCH ASSOCIATION TO PREVENT THE ABUSE OF TOBACCO AND ALCOHOL.—An association with the above name has been organized in Paris, M. Frederic Passy being President. A prize of 200 francs and a medal is offered for the best work showing the evil effects, moral and physical, of the abuse of tobacco and alcohol.

A NATIONAL BUREAU OF VETERINARY INSPECTION.—At the annual meeting of the American Veterinary Association, held recently in this city, a proposition to establish a National Bureau of Veterinary Inspection was made. It was proposed that the bureau have similar powers, as regards animals, with those possessed by the National Board of Health. The disease which, it is thought, more especially calls for such an organization is pleuro-pneumonia. It is urged that recent events have shown how valuable it would be to large commercial interests to have a central bureau that might keep cattle dealers and shippers constantly informed as to the prevalence of contagious diseases. Such an arrangement would prevent panics and render impossible the prohibition of American cattle by European governments upon mere sensational reports.

It is, on the other hand, said that such information

can be secured without government aid. Furthermore, the present status of veterinary medicine is so undefined that a National Bureau would not have much more of a legitimate professional basis than a National Bureau of Barbers to keep themselves informed upon sycofancy. There is in this country only one veterinary college which exists under legislative sanction, and which can grant genuine diplomas. Veterinary practitioners, therefore, are composed of three classes: persons who have graduated from regular foreign and the one regular home school; persons who have graduated from other home schools and have received diplomas which are virtually only certificates; and, third, persons who have had no regular education whatever.

It is feared that the establishment of a National Bureau out of these elements would produce endless quarrelling without securing any valuable results.

DR. E. S. GAILLARD, the distinguished editor of the *Richmond and Louisville Journal*, and *American Medical Bi-Weekly*, has removed to this city, where he will reside in future. His journals will also claim New York as their abiding place. With best wishes for his success, we extend to him, on the part of the profession here, a hearty welcome.

TRACHEOTOMY FOR SAND BURR IN TRACHEA.—Dr. J. B. Hibben, of Topeka, Kansas, writes: "On Saturday, August 27th, I was called, in company with Drs. Sheldon and Gibson, to see a boy of six years. Upon examination, found that he had, two days previous, while playing with a tin whistle, drawn into his trachea a large 'sand burr,' which produced severe coughing, with partial asphyxia, having almost complete aphonia and great difficulty of breathing. We found mucous râles in the lungs, with diaphragmatic breathing; being confident that the foreign body was still in the trachea, the child was etherized, and tracheotomy performed, which permitted free and easy breathing. The foreign body not presenting itself at the opening, a tracheotomy tube was introduced for half an hour, then removed, and a small, soft sponge-probang introduced through the wound upward, dislodging the burr and pushing it forward into the mouth, from which it was easily removed. The patient made a rapid and favorable recovery, the wound healing by first intention."

FATAL RESULT IN THE TREATMENT OF POPLITEAL ANEURISM WITH ESMARCH'S BANDAGE.—When a new surgical procedure is introduced, the cases in which it fails should not be overlooked, and we therefore make note of one that is reported in the *Lancet* of July 26th. A patient, aged forty-eight, was admitted to St. Bartholomew's Hospital, suffering from a popliteal aneurism of eight months' standing. He was under the care of Mr. Timothy Smith. He was treated by Esmarch's bandage, both with and without chloroform, with the result of twice stopping the pulsation, which, however, soon returned. After waiting a few days another trial was made. The elastic bandage was applied below and above the tumor, which was itself covered by a flannel bandage. These bandages were removed in an hour, and digital compression and the tourniquet applied for three hours. Then the elastic bandages were reapplied for an hour and a half, and at the end of that time, the tourniquet being put on, they were removed, and the tumor was found to be solid. In a short time, however, pulsation returned. Bandage and tourniquet were again applied, until the leg was too tender and painful for further treatment of this kind. The tumor continuing to pulsate, the femoral was ligated; secondary hem-

orrhage occurred, and it was ligated again, but the man died with evidences of septicaemia.

The chief peculiarity about the case, pathologically speaking, was the unstable nature of the clot obtained by compression. The man had heart disease, and had had syphilis, and these were probably factors in producing the result.

LIME-WATER AS A SOLVENT OF BLOOD CLOTS IN THE URINARY BLADDER.—Dr. William A. Byrd, of Quincy, Illinois, writes: Dr. B. W. Richardson and other writers have advocated systemic alkaline treatment for heart-clot, and some of the German writers have proposed and used lime-water as a solvent of false membrane in the air-passages, but I believe that Dr. J. H. Ledlie, of Pittsfield, Illinois, is the first to apply lime-water locally to blood-clots in the bladder to cause their dissolution. Having perfect faith in Dr. Ledlie's ability, and considering the treatment to be of great value in cases of blood-clot, is my excuse for publishing his letter to me, that the reader may judge of its value:

"PITTSFIELD, ILLINOIS, Sept. 19, 1879.

"DEAR DOCTOR—I have a patient, a man who for years has suffered greatly from hematuria. The blood comes from the kidneys. At times the hemorrhage is very profuse, and clots in the bladder. Heretofore I have always succeeded in washing it out with a double-current catheter. Last Saturday I was called to see him. He had lost a great quantity of blood, and was suffering very much from vesical tenesmus. I passed my catheter and injected a stream of water. All at once the stream returning would stop. By withdrawing the instrument I could start it again, but he insisted there was a foreign body in there. I must say, that the previous day he had experienced excruciating pain along the course of the ureter. I suspected stone and sounded him, but could not discover one; still my instrument touched something. I repeated the washing out of the bladder until the water returned colorless. I then made up my mind that there was a clot, with the coloring-matter washed out; and recollecting your account of dissolving the false membrane with lime-water, I threw in one-half pint of lime-water, allowing it to remain half an hour. When it passed off it resembled what you describe as the appearance of the false membrane after lying in lime-water. He also passed a large piece of fibrin which had evidently been acted on by the lime-water, although not sufficiently so to dissolve it entirely. Had it not passed away, I am convinced another injection would have dissolved it entirely. He is now quite comfortable, all sense of a foreign body in the bladder having passed away. J. H. LEDLIE."

ANÆSTHESIA FROM THE COMBINED ACTION OF CHLOROFORM AND MORPHINE.—A review of the present state of evidence upon this question has been given by Dr. Guibert, of Paris, in *Le Concours Medical*. The French surgeons consider that all the danger in the use of chloroform comes from producing too profound unconsciousness. It has been the aim of a number of experimenters to bring about in every case a condition of anæsthesia, with consciousness still continuing; such a condition as occurs not very rarely during ordinary administrations. The administration of morphine before the chloroform tends, it is thought, to secure this result.

It is claimed further, that morphine employed before chloroform diminishes the irritation to the air-passages, caused by the anæsthetic vapor, an irritation which, by its reflex influence upon the heart, may

prove dangerous. Finally, it is asserted that when morphine is given before the chloroform the danger from shock is much lessened, and that the frequency of vomiting is also diminished. The procedure followed by the believers in these statements is, to give a quarter of a grain of morphine; then in ten or fifteen minutes to administer the chloroform. Analgesia is produced sometimes within two minutes.

It should be remembered by American practitioners who use ether, that death has occurred from using morphine in connection with that anæsthetic.

MEDICAL EXPERT TESTIMONY: ITS DEFICIENCIES.—The *Boston Medical and Surgical Journal* publishes the first part of a report upon this subject made to the Massachusetts Medico-Legal Society in June last. The committee appointed to examine the subject included Attorney-General Marston (chairman), and Prof. H. P. Bowditch. Their report was only partial, and embraced a statement of the evils that encumber the present system of medical-expert testimony. These are: first, a most conspicuous partisanship, even in questions of a purely scientific character, the experts being practically retained upon one side or the other, and expected to help that side; second, the employment of pretenders and charlatans; third, the fact that the expert's compensation often depends upon the result of the trial; fourth, a lack of integrity on the part of the expert, even when he is a person of ability. Finally, although there are experts who are both honest and able, there is no system by which their services can be equally applied, for only the party which has money can secure such persons, and the other side must get what they can. The committee have been granted further time to devise measures of reform for this condition of affairs.

A NEW MEDICAL COLLEGE has been organized at Little Rock, Arkansas, to supply a want long felt.

DIPHtheria IN LOWER ANIMALS.—In a house at Ogdensburg, N. Y., five children were ill with diphtheria. Three kittens who had been playing with them from time to time took the disease and died. Post-mortem examination showed diphtheritic membrane in their throats.—*Medical and Surg. Journ.*

CHLOROSIS; TREATMENT WITH OXYGEN AND IRON.—The researches of M. HAYEM, as given in *Le Concours Medical*, covering several years, demonstrate that in chlorosis there is not only a diminution in the number of red blood-globules, but an individual alteration of each globule. This alteration consists of a diminished amount of the coloring matter hæmoglobin. Iron has a specific action in removing this condition.

As in chlorosis there is generally loss of appetite, and as the preparations of iron stimulate the appetite, it has been claimed that the good they do is largely through this means. To disprove this, M. Hayem treated a number of patients with insoluble preparations of iron, without relieving the disease. He then treated other patients with inhalations of oxygen, giving about three gallons a day. The oxygen had a marked effect in stimulating the appetite and digestive functions. The patients ate enormously, and increased in flesh; nevertheless, they preserved their pallid and anæmic appearance. The microscopic appearances of the blood continued the same, and on suspension of the oxygen they soon relapsed to their former condition. M. Hayem concludes that iron alone can restore the red blood-globules to their natural condition, and that oxygen is a most valuable adjuvant in the treatment.

Original Lectures.

A CLINICAL LECTURE ON
URINARY INFILTRATION AND ABS-
CESS.

By ROBERT F. WEHR, M.D.,

SURGEON TO THE NEW YORK AND ROOSEVELT HOSPITALS.

GENTLEMEN:—I have been able to show you in the past month several cases of urinary abscess and extravasation. They have, however, varied so considerably in their clinical appearances, that it is proposed to-day to ask your attention to certain points connected with this subject, somewhat more in detail than has yet been done. You have seen in Ward O a number of cases in which an oval tumor, generally without fluctuation, presented itself in the median line of the perineum, with its longest diameter antero-posteriorly, sometimes very tender to the touch, and varying in size from a small marble, in one instance, to a hen's egg, in several others. Nearly all of these were associated with stricture of the urethra, and after incision allowed urine to flow out through the wound. In one case, however, the tumor resulted from a laceration of the urethra produced by a kick in the perineum.

In the same ward, and only recently, you saw a case wherein was presented a scrotum swollen to the size of a child's head, shining from distention, and of a pinkish, semi-transparent hue, which had followed, as the patient said, one of these swellings in his perineum. You were, however, more struck with the appearance presented by Thomas Graham, who entered the hospital on the 25th of August, having some twenty-four hours previously been kicked in the perineum. In this man we found not only the scrotum distended enormously, but that its surface was marked by greenish patches of commencing gangrene, and that upon the lower abdominal wall were to be seen several streaks of redness. Palpation also revealed the emphysematous crackling of the gases evolved in the rapidly progressing inflammation and tension, and, you will recollect, that, notwithstanding the free incisions resorted to, a fatal termination speedily ensued.

Some of you may also remember in this connection the interesting case that came in last spring to my wards in the Roosevelt Hospital, where the patient, who had a tight stricture, had also a large tumor in the perineum, and two good-sized patches of gangrene, accompanied by emphysema, on the abdomen, the lower part of which was moderately reddened, and in one or two places gave evidence of fluctuation. But, and be kind enough to mark this, there was no involvement of the scrotum whatever. The perineal tumor could be felt running forward beneath the scrotal tissues, and on incising it several ounces of clear urine were discharged from it. The finger was then passed into the cavity, which was bounded by the sheath of the penis, and carried upward nearly its full length, and after freely incising the gangrenous patches on the belly, and giving vent to a quantity of the same almost unaltered urine which had dissected up the common fascia, a second finger introduced downward could touch the finger introduced from the perineum at the left side of the penis, near the scrotum. This case terminated favorably.

Lastly, I beg to recall to your minds the patient who was knocked down on the elevated railroad by an engine, the blow being received on the posterior part of

the perineum, the man being at the time in a stooping position. In his case, you will recollect, there was hemorrhage from the urethra and inability to pass water, though the house-surgeon passed in a catheter full length without difficulty, but without evacuating any urine. This failure was thought to be due to the eyes of the instrument being filled up with clotted blood, and, finding some dullness on percussion over the pubis, he then resorted to aspiration, and withdrew some five or six ounces of bloody urine. When I saw the man at my visit, I thought from the latter fact and from the tenderness of the abdomen and tympanites that were coming on, with the other signs of peritonitis, such as vomiting, etc., that we had to deal with a case of ruptured bladder, and it was therefore decided that a perineal cystotomy should be made, with, if necessary, a hypogastric opening into the peritoneum, for the purpose of washing out and draining this latter cavity, after closure of the rent in the bladder, if possible, as has lately been done by Mr. Heath, of London. But death resulted unexpectedly during the administration of the ether, from an infrequent cause, viz., from impaction of food in the larynx in the vomiting which is often induced by the anæsthetic when given upon a full stomach.

No autopsy was allowed, but I was permitted to make an incision in the hypogastrium. I found thereby the explanation of the injury. For, after cutting through the muscular planes, I came into a cavity containing over four ounces of bloody urine, but beyond this I felt and soon opened into a partly distended bladder containing eight or ten ounces of clear urine. The aspirator-needle, therefore, had not gone into the bladder, but into a subperitoneal cavity. On passing my finger into the bladder, I could not feel anywhere any rent; its walls were intact. While my finger was yet within the organ, I had a catheter introduced through the penis, and recognized that it could be passed to the left and also to the right of the bladder, into spaces that were probably continuous with that in the hypogastrium.

These numerous cases show, clinically, that extravasation of urine can occur in four ways:

1. Localized as a centrally situated tumor in the perineum.
2. As a tumor of considerable size in the perineum, with diffusion of urine over the abdominal walls without involving the scrotum.
3. Diffused into the scrotal and abdominal tissues.
4. Diffused under the pelvic fascia or peritoneum.

Now, to understand these several varieties, certain anatomical facts must be recalled, and this is in reality the point of my remarks. Generally, in the works on anatomy in use here and in England, the description of the fascia of the perineum is given in this way—I quote now from Gray: "The deep layer of the superficial fascia is thin, aponeurotic in structure, and of considerable strength, serving to bind down the muscles of the root of the penis. It is continuous in front with the *dartos of the scrotum*; on either side it is firmly attached to the margins of the rami of the pubes and ischia, external to the crus penis and as far back as the tuberosity of the ischium; posteriorly it curves down behind the transversus perinei muscles, to join the lower margin of the deep perineal fascia."

But this account is erroneous, and in order that you may understand the course of the perineal fascia in connection with extravasation of urine, I must beg you to follow me in these diagrams which I now show you. No. 1 represents schematically the points

which you will find only clearly detailed in the more recent works on genito-urinary surgery. No. 2 is taken from Tillaux.* I do not mean to say that Tillaux re-

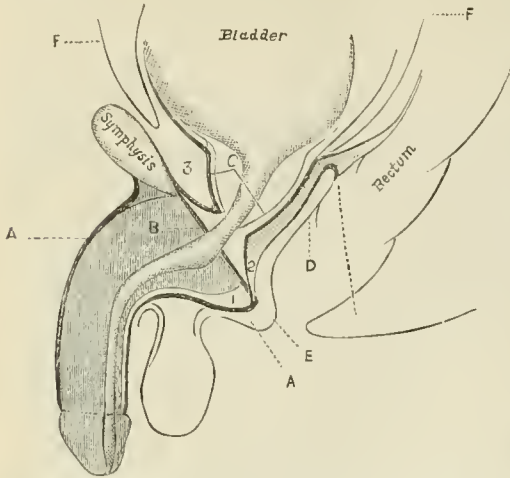

FIG. 1.—Representing the fasciæ involved in urinary infiltration (partly schematic). 1. Locality of extravasation of urine anterior to the triangular ligament; 2. Locality of extravasation of urine posterior to the triangular ligament; 3. Locality of Subperitoneal extravasations; A. Buck's fascia, or deep layer of the superficial perineal fascia; B. Triangular ligament, anterior layer; C. Pelvic fascia forming posterior layer of the triangular ligament and covering upper surface of the levator ani muscle; D. Fascia (ischio-rectal or anal) lining under surface of levator ani muscle, the dotted line indicates the ischio-rectal fossa; E. Tendinous centre of the perinæum; F. Reflexion of peritonæum, attached posteriorly to the pelvic fascia.

vealed these facts to us. They were known long, long ago. Velpeau, in 1826, correctly described the distribution of the fasciæ.† And so did Richet‡ in 1842. But it was not until it was demonstrated to us by Dr. Buck, of this hospital, in 1846,§ that it became generally known. After that period the French surgeons described it as Buck did, or very nearly so—Jarjav, one of the most distinguished of their anatomists, giving the American surgeon due credit for his investigations. Since then it has been regularly and correctly delineated by Cruveilhier and others of that school, but in England very little attention has been given to it. For instance, Thompson,|| in his work on stricture of the urethra, that fountain whence we all draw, speaks of the forward continuation of it as Gray does, and erroneously explains the course of such infiltrations and abscesses. On our side of the water, however, Bumstead quotes Dr. Buck's description in extenso, and Van Buren and Keyes describe it carefully. Now let us return to the diagram, and see wherein this differs from Gray. Notice the black line indicating the deep layer of the superficial perineal fascia. Instead of being lost in the scrotum, it runs forward from its junction with the triangular ligament, covering over all the perineal muscles, except the sphincter ani, and is continued along anteriorly as far as the glans penis, being closely applied to the sheath anterior to the scrotum. Or, in Dr. Buck's language, observe that "the suspensory ligament from above, and the perineal fascia from below and laterally, form one contin-

uous membrane with the sheath, inclosing the corpus cavernosum in its cavity, and embracing the corpus spongiosum urethrae between two layers, one of which passes above and the other below it."

Here we have a satisfactory explanation of the numerous perineal tumors which you have seen, and which were embraced in our first and second divisions. The small extravasation resulting, say, from the giving way of the urethra, behind a stricture from either ulceration or from injury by an instrument, escaping from an opening thus made at its usual locality anterior to the triangular ligament, passes into this pouch that has just been described, and is there held for a time, when by distention or by inflammatory softening, the fascia gives way and allows the urine entrance to the scrotum and to the abdominal walls.

It occasionally happens that an extravasation forces itself into the tissues of the bulb of the corpus spongiosum so rapidly, or so extensively, as to interfere with the circulation of the glans, and to produce the characteristic gangrenous spot there.

But I must ask you now to consider for a moment this second figure. From it you will see that while the pouch or compartment formed by this forward fascial prolongation stretches from one pubic bone to the other, yet it is divided into three portions by the continuation of a part of the fascia around the bulbous part of the corpus spongiosum to the triangular ligament. In the outer compartments are to be found the erectors penis muscles. I also show you this dissected specimen, in which it will be perceived that I have forced some melted tallow under this fascia, just in advance of the transversus perinei muscle of one side.

FIG. 2.—Representing a horizontal section of the perinæum—after Tillaux. BF, Buck's fascia; * Fascia investing the bulb of the corpus spongiosum (B), and dividing the enclosure into a middle and two side compartments; U, Urethra; CG, Cowper's glands; AU, Accelerated urine muscle; TL, Triangular ligament, anterior layer; PF, Pelvic fascia or posterior layer of the triangular ligament; CU, Compressor urethrae muscle; CC, Corpus cavernosum; EA, Erector penis muscle; DRP, Descending ramus of the pubis; FS, Fascia superficialis communis; S, Skin.

The fascia, although a thin one, is quite strong, and you can plainly see the colored injection beneath. It runs as far forward as the anterior junction of the scrotum, and is confined, you see, to the central part for the cavities containing the erectors have been opened and are free from the injection. Over the bulb an incision has been made, and you will see that the tallow has lifted up the accelerator urine, and thus the resisting power of the fascia is increased.

The explanation of the ease of extravasation, where there was a tumor in the perinæum and where there was at the same time invasion of the abdominal wall and not of the scrotum, is to be found in the statement of Richet, who, in alluding* to Dr. Buck's

* *Op. et loc. cit.*

investigations, differs in two particulars: first, that the fascia is not distinct up to the glans penis, and in this, as before stated, I agree with the French observer; and second, that, instead of Buck's fascia, as it is called, completely investing the penis, this fascia in the neighborhood of the suspensory ligament thins very much, and terminates in a cellular tissue continuous with and undistinguishable from the fatty and cellular layer of the hairy pubes.* It was by this route, therefore, that the urine gained the abdomen without involving the scrotum.

If I have not fatigued you with these minutiae, I would now like to ask your attention, before explaining to you the last cited case, to the posterior layer of the triangular ligament in our first diagram. There you will see that this layer is in reality formed by the prolongation of the pelvic fascia forward from the prostate, which fascia, moreover, covers in *superiorly* the levator ani muscle. The inferior border of this posterior layer of the triangular ligament, you will see, terminates on a line with the tendinous centre of the perineum; from this point starts, moreover, backward and upward, a thin, weak, and in some places an imperfect fascia, which lines the *under* surface of the levator ani, and runs up to the top of the ischio-rectal fossa. Hence, you can appreciate that any extravasation of urine, or abscess formed behind the anterior layer of the triangular ligament—that is to say, in the erroneously called cavity of the triangular ligament, will, from inability to pass forward from the great resistance there found, proceed backward through the posterior layer, here much thinner, and then into the substance of the levator ani, and thus readily find entrance to the ischio-rectal fossa, where it may be for a time unrecognized, or emerge at the anus.

Cases of this sort are very rare—more so than most of you would imagine; for doubtless the idea is prevalent with you that strictures are commonly found in the membranous portion of the urethra, and that the rupture or ulceration that initiates an extravasation, being generally behind such narrowings of the canal, infiltrations or abscesses must of necessity occur behind the anterior layer of the triangular ligament. This is a wrong impression, if it exists, for the membranous urethra is rarely, if ever, the site of stricture; † on the contrary, it is the bulbous urethra, for one inch anterior to the triangular ligament, that is the favorite site of tight strictures, and the nearer one approaches the bulbo-membranous junction the less frequently is a stricture encountered. Not only is this true of inflammatory strictures, but also of traumatic strictures.

This latter fact has recently been clearly demonstrated for us by a French observer, Terillon by name, in an excellent thesis on Ruptures of the Urethra.

I have myself never seen any tumor that presented clinical evidences of being between the layers of the triangular ligament, and, indeed, would be inclined to doubt the accuracy of those who describe such,

mainly from the intimate adhesion that exists between the layers of this ligament. I should expect to find in such a case a small deep tumor close to the anus (for the tendinous centre is less than half an inch from this opening), and also by the finger introduced into the bowel to readily recognize the swelling in the easily felt site of the membranous urethra.

Practically, when a urinary abscess or infiltration occurs behind the triangular ligament, its starting-point is generally a false passage made by incautions instrumental manipulation. An instructive illustration of this was seen in a case that occurred a short time since in the Roosevelt Hospital, in a patient who shortly after his entrance complained of retention of urine, which he said had followed the use of dilating bougies used within a couple of weeks. He had had repeated chills, but no perineal tumor was to be detected. After aspiration had been resorted to several times, a fine filiform bougie was introduced into the bladder, and external perineal urethrotomy performed rather than internal urethrotomy, as a small amount of edema and softness over the side of the prostate led us to expect at the same time to meet with an abscess. In fact, after incising the urethra in front of the stricture, it was found that the bougie had not gone through the latter, but alongside it in a false passage, through which pressure in the rectum forced out a few drops of pus. This path was enlarged backward and allowed the escape of several ounces of pus from a cavity into which the finger passed well up toward the bladder, and traced out clearly the surface of the partly denuded rectum. A drainage-tube was inserted into the pus-cavity after the section of the stricture had been completed without a guide—and thus making the second time I have ever been compelled to resort to perineal section.

Finally, gentlemen, the explanation of the case of subperitoneal extravasation is, that the injury inflicted, coming as it did from behind forward, tore through, in all probability, the membranous urethra and its superior investment of the pelvic fascia, and thus opened up a way underneath the peritoneum for the fluid to pass (indicated by the figure 3 in diagram No. 1). This injury is an unusual one, and I regret that the absence of an autopsy prevents any positive statement as to the course of the urine, for, had I not had the opportunity to explore the bladder, I should have, as before stated, thought it a rupture of this viscus. Whether the laceration had been caused by a fracture of the ramus of the pubis, which is the usual cause of lacerations in the membranous urethra, could not be determined. Remember, however, that subperitoneal infiltrations are most commonly the result of either a lesion of the bladder or possibly from a too extensive incision in the prostate in lithotomy.

It will be understood by you all, I trust, that the more minute the opening is in the urethra, or the more slowly the urine is forced out of its normal channel, the more likely is the inflammatory process to limit the extent of the infiltration, and to confine it within the bounds of the ordinary urinary abscess. It is in the rupture of a urethra with the associated great pressure of a distended bladder that we are most apt to see the rapid spreading of the urine, mopping out for us distinctly the enclosing fasciæ. Finally, these remarks may be summarized in this way: first, that nearly all, if not quite all, perineal extravasations occur from ruptures anterior to the triangular ligament; and second, that a fistulous opening anterior to the line of the tuberosities of the ischia comes, in all probability, from the urethra, and when behind this line, from the rectum.

* Tillaux says, it is imperfect on the dorsum of the penis, at the level of the suspensory ligament, p. 1040.

† Richet says that it is by this route that the urine usually gains the scrotum, but it can also infiltrate these tissues by perforating Beck's fascia by ulceration.

‡ The liability of this part to stricture appears to diminish as it approaches the junction, where it is less common; while behind this point it probably never exists, except from traumatic cause. In 215 cases of stricture in this region, only one was found in the membranous urethra.—Thompson: Stricture, 3d edition, p. 38.

§ Shaw, Med. Chir. Trans., vol. XII, states that in more than a hundred dissections he had not seen a stricture or narrowing of the canal posterior to the triangular ligament.

¶ Picard, Maladies de l'urethre, p. 448, says, concerning infiltrations of urine, that the most frequent place of rupture is in front of the membranous region, and that the extravasations advance nearly always into the "inferior pocket of the perineum" (Buck's fascia).

Original Communications.

REPORT OF THE RESULTS IN
THIRTY-ONE CASES OF PHTHISISTREATED AT AIKEN, S. C., DURING THE SEASON
1878-79.

By W. H. GEDDINGS, M.D.

AIKEN, S. C.

THE climate of Aiken has been often and fully described, but thus far the results of treatment at that well-known health-station have never been laid before the profession.

The publication in the *MEDICAL RECORD* last spring, by Prof. Loomis, of a few cases successfully treated in the Adirondack region, determined the writer to carry out a resolution made several years ago, to publish each year the results in all the cases of consumption that came under his observation in the course of the season. In preparing these cases for the press, it was found, however, that some of them were so imperfect—the patients presenting themselves only once or twice—that their publication would be only a waste of space. The number thus omitted is quite considerable, constituting the large majority of cases presenting themselves for advice. The case histories are taken from my daily record; and not being intended at the time of their entry for publication, the symptoms given are, in many instances, more or less incomplete. It is thought, however, that they are sufficiently full to remove all reasonable doubt as to the diagnosis of the disease, its stage of development, and the results of treatment. Being exclusively private patients, the writer has not felt at liberty to give their names, or even their initials; but they may, in nearly every instance, be recognized, and, if necessary, verified by the name of either the attending or of the consulting physician, which, as a rule, is given immediately after the number of the case. Some few of the cases have been under observation for several years; while others, and by far the larger number, were treated for a few months only. It is needless to state that the greatest care has been taken to make the report as correct as possible; and to secure this end, many cases were omitted, in which, although they presented general symptoms sufficiently marked to warrant their being classed as phthisis, the physical signs of that disease were either wanting or of a doubtful character. As this class usually represents cases in the initial stage, which are, of course, more amenable to treatment than those farther advanced, their omission materially reduces the number of successful cases, a fact which should not be forgotten in estimating the general result.

CASE I.—Male, 41 years, patient of Dr. Paddock, of Lenox, Mass. Disease began with bronchial catarrh in the winter of 1877. Patient visited Aiken for the first time in Jan., 1878, previous to which he had lost 14 lbs.—his weight, when he arrived in Aiken, being 122 lbs. He had also had occasional night-sweats. At that time there was dulness on the left side, extending from the clavicle to the fourth rib in front, and half down the scapula behind, the respiration being bronchial in character. Up to the 21st of March of that year, he had gained 4 pounds in weight, and his general appearance was much improved. The expectoration was greatly reduced in

quantity. He passed the summer at Lenox, attending to his business, which was that of a grocer.

Dec. 31, 1878.—Patient's weight is 126 lbs., color healthy, pulse 92, temperature $98\frac{1}{2}^{\circ}$; expectoration half an ounce, some of which sinks. On the left side the dulness extends from the clavicle to the third rib, showing a diminution in the extent of the infiltration since the first examination. On the back there is no change in the area of dulness. Expiration prolonged. Bronchophony. Patient neglected to take care of himself, ceased taking the remedies prescribed, and for a time lost ground.

April 21st.—Dulness in front unchanged, but behind it is reduced to a small space above the spine of the scapula. Respiration bronchial. General health much improved. A letter received a few weeks after his return home states that the improvement has continued.

CASE II.—A middle-aged male from Washington, D. C., a patient of Dr. S. C. Busey, of that place. This case, which has pursued a very chronic course, dates from boyhood; has always had more or less trouble with his respiratory apparatus. He consulted me for the first time in December, 1875. He then had an infiltration of the right lung, as evidenced by dulness between the scapula and vertebral column. The patient had just returned from Florida without having derived any benefit from his residence there.

Several years ago he contracted a croupous pneumonia, involving the affected lung; was for a time quite ill; but, after resolution had taken place, there was no change in the size or character of the chronic infiltration. He has been an annual visitor to Aiken for the past five or six years, and always derived much benefit from its climate; but this year (1879), being in Savannah, he concluded to give Eastman a trial. While there he had a succession of hemorrhages, which reduced him to such an extent, that Dr. Busey was summoned from Washington to him. Yielding to the urgent entreaties of the patient, Dr. B. had him conveyed in a special car to Aiken. He had one or two hemorrhages on the way, and, at the time of his arrival, was so prostrated, that he had to be brought on a bed from the cars to the hotel. His condition at that time was such as to cause his friends the greatest anxiety.

Jan. 19, 1879. Physical examination reveals dulness on the right side, extending over the supra-scapular and upper half of the infra-scapular region. Respiration bronchial, and at some points distinctly cavernous. On the left there is marked dulness behind, with prolonged expiration. He had but one hemorrhage after his arrival in Aiken, and from that time on, the course of the disease was one of very slow, but steady and uninterrupted improvement. For a long time he had to be rolled about in a chair, and many weeks elapsed before he entirely regained the use of his limb.

April 15th.—The patient is much improved, having gained in weight and strength. He can now walk about, and may be said to be as well as he has been during the past two years.

CASE III.—Male, 52 years of age, a patient of Dr. F. Donaldson, of Baltimore. Many years ago patient had rheumatism, with cardiac complication. Last July (1878), after taking a prolonged hip-bath for the relief of hemorrhoids, he had a severe chill followed by fever, which continued to recur until September, at which time he began to cough.

Jan. 24.—Pulse 112, temperature 102° . Over the left front there is diminished resonance from the clavicle to the fourth rib, with marked dulness under the

scapula of the same side. Breathing decidedly bronchial, with loud expiration. During the month of February was troubled with palpitations and pain in the cardiac region, and complained of great weakness and giddiness. No abnormal murmurs could be detected, but the œdema of the limbs in connection with the above symptoms indicated the existence of some serious cardiac lesion. There was some improvement in the condition of the patient until March 4th, at which time there was an exacerbation of the disease, with increase of fever, sweats, etc. Physical examination revealed dulness on the right side with bronchial respiration. The cardiac symptoms also became more troublesome. April 15th, there being no prospect of improvement, the patient was advised to return home.

CASE IV.—A young lady from New Jersey; Dr. Hayes Agnew, of Philadelphia, consulting physician. The neck much disfigured with large cicatrices, the result of scrofulous ulceration of the cervical glands. Has lost flesh; lies on the left side.

Jan. 28.—Pulse 96, temperature $101\frac{1}{2}^{\circ}$; diminished resonance over the upper portion of the right lung, with jerking, bronchial respiration. Feb. 26th.—Pulse 104, temperature $101\frac{1}{4}$. Dulness distinct under right clavicle, with audible expiration anteriorly as well as posteriorly. On the left side there is no dulness, but the respiration is bronchial in character. The patient gradually grew worse, returned home at the close of the season, and died in August.

CASE V.—A middle-aged clergyman from Gloucester, Mass., a patient of Dr. Morrill Wyman, of Cambridge. Disease commenced with bronchial catarrh in April, 1878. Has had one slight hemorrhage.

Feb. 1, 1879.—The upper portion of the thorax on the right side is much depressed. There is an extensive area of dulness occupying nearly the whole front of the right lung. There is also dulness behind, but not so extensive as in front. March 7th.—Much improved, coughs less, but the expectoration continues profuse. Has a good color, and has gained eight pounds. March 13th.—Patient looks fresh and ruddy; pulse and temperature all but normal. Expectoration still profuse. April 9th.—Pulse 84, temperature, $98\frac{1}{2}$. Coughs much less, and the expectoration is reduced to a fourth of what it was a month ago. April 26th.—Pulse 84, temperature 99° . Has continued to improve; has gained four pounds since last examination. May 20th.—Had an attack of diarrhoea a week ago, which caused him to lose six pounds, three of which he subsequently regained. He now weighs nine pounds more than he did when he arrived in Aiken. There is diminished resonance, not amounting to positive dulness, extending from the clavicle to the third rib, over which region the respiration is normal, the expiration being barely audible. He coughs little, except in the morning, at which time he expectorates two or three drachms of mucopurulent matter.

CASE VI.—A bright little girl of six or seven years, Portsmouth, N. H., who, being under the care of a homœopathic practitioner, consulted me only occasionally, so that her case history is more or less imperfect. The disease was the result of an attack of pertussis.

Nov. 6, 1878.—Pulse 120, temperature $99\frac{1}{2}^{\circ}$. The right lung is infiltrated from the apex to the fourth rib, as evidenced by distinct dulness both in front and behind.* This patient did remarkably well until Feb. 1st, when she had an attack of bronchial

catarrh. She recovered readily from this, and continued to improve until late in the spring, when she was lost sight of.

CASE VII.—A married lady, patient of Dr. McBurney, of New York. Disease started with bronchial catarrh in Feb., 1877. Lost flesh, at first quite slowly, but, diarrhoea supervening, the emaciation progressed very rapidly.

Feb. 10th.—Pulse 100, temperature $100\frac{1}{2}$, in afternoon as high as 104. Expectorates several ounces; is very anæmic, and has had but little strength. Physical examination reveals extensive disease of the left lung, with softening of tissue. The advanced stage of the disease, the high temperature and great emaciation, precluded in this case all hope of improvement. She remained a few weeks in Aiken and then returned to New York.

CASE VIII.—A young lady, 24 years of age, from an adjoining county, in regard to whose case Dr. Hydrick, her medical attendant, kindly furnished the following history: "The patient came under my observation about one year ago. Her previous history is one of pulmonary disease of several years' duration; had hemorrhage in Oct. (1878). The family history is not good; her mother, sister and brother having fallen victims to pulmonary disease." The disease was ushered in with hemorrhage in the spring of 1877. Has had "asthma" since her childhood. After this attack she was ordered to Florida, but on reaching Charleston she consulted the late Prof. Geddings, who informed her that her native air was preferable. Under his treatment she improved, and remained in fair health until Oct. 1, 1878, when she had several hemorrhages and lost fifteen pounds.

Feb. 11th.—Patient is rather pale; pulse 110, temperature $100\frac{1}{2}^{\circ}$. Has night-sweats. On the right side there is dulness under the scapula, with feeble respiratory murmur and occasional bronchi. On the left the respiration is bronchial in character, with loud prolonged expiration. At the base of both lungs there are evidences of emphysema. March 15th.—Pulse 92, temperature $99\frac{1}{2}$. Patient looks much better. March 31st.—Patient returns home much improved, is stronger, has a better color, and coughs less. Has increased several pounds in weight. The dulness on the right side is of course still perceptible, but the mucous râles have entirely disappeared. On the left side, to the outer side of the heart, the respiration is still bronchial in character.

CASE IX.—Male; patient of Dr. Büchler, New York. Had an attack of hæmoptysis in 1860, with cough of several months' duration, from which he recovered completely, and remained perfectly well until August, 1878, when he again commenced to cough.

February 18, 1879.—Patient has lost five pounds since the attack in August, and looks quite pale and sallow. Pulse, 104; temperature, 99° . On the left side, and to the left of the heart, the percussion sound is short, and the expiratory murmur prolonged. Over the back the respiration on that side is very harsh. On the right side there is dulness over the apex, the respiration being quite feeble.

March 4th.—Color much improved; coughs less, and has gained one pound.

March 27th.—Has had slight attacks of congestion, with tingeing of the sputa, but now feels quite well.

April 23d.—Is stronger and expectorates less. The dulness, however, is much more distinct, extending on the right as low as the second rib.

April 29th.—Patient goes home improved in general health, but without any material change in the local symptoms.

* The symptoms afforded by auscultation were accidentally omitted.

CASE X.—A married lady, patient of Dr. George C. Webber, of Millbury, Mass., who writes that "she has incipient trouble in one lung," and "that she has lost three sisters by phthisis."

February 24th.—Color pale; pulse, 120; temperature, $98\frac{3}{4}^{\circ}$. On the right side there is dulness on percussion below the clavicle, with bronchial breathing over the upper portion of the lung. Left side dull under the clavicle.

March 20th.—Pulse, 104; temperature, $100\frac{1}{2}^{\circ}$. Has gained seven pounds in weight, and is greatly improved in color. Left apex still dull. On the right side the dulness is still present, but greatly diminished in extent.

April 8th.—Has continued to improve; has gained two pounds additional during the past month, making a total gain of nine and a half pounds since her arrival in Aiken.

May 2d.—Pulse, 104; temperature, $99\frac{1}{4}^{\circ}$. Coughs and expectorates much less; weighs more than she ever did in perfect health. The area of dulness is still present, but the respiration is all but normal.

CASE XI.—March 1st, a young man, eighteen years of age, a patient of Dr. P. Donaldson, of Baltimore. His father, two uncles, and an aunt had consumption. Has frequent attacks of hæmoptysis; has morning exacerbations of fever, and sweats at night. On the right side, the percussion sound is dull. The expiratory murmur is prolonged over the front and back. Vocal fremitus quite pronounced on that side. March 17th, no returns of the bleeding since the 8th; the morning paroxysms of fever have ceased to recur, the temperature never rising above $98\frac{1}{2}^{\circ}$; coughs only occasionally, then only after exerting the voice.

May 12th.—Goes home much improved; has had no return of the hemorrhages; has gained three pounds, and is much stronger.

CASE XII.—A young German, a patient of my own, who removed to Aiken in 1874, with an infiltration of the apex of the right lung. He had had several attacks of hæmoptysis, and presented all the symptoms of the first stages of phthisis. He improved rapidly, but, disregarding my advice, he accepted a situation in a store, where the confinement soon brought on a return of the old symptoms. He abandoned his position, and after drinking the blood of freshly slaughtered animals for several weeks he regained the ground he had lost. Remarkable his rapid improvement while drinking fresh blood, he was advised to change his occupation and become a butcher; but instead of this he unfortunately opened a bar-room, where the irregular life, late hours, and constant exposure to cold draughts, favored the development of laryngeal phthisis, with extensive ulceration of the vocal cords. He grew gradually worse, and at the close of the last season was apparently very near his end. The chronic course of the disease (seven years), and the repeated arrest of the process, led to the belief that, had he exercised common prudence, his life might have been prolonged many years, and that there was in his case even a fair chance for a permanent arrest of the process.

CASE XIII.—This patient, a young lady from New Rochelle, was far advanced in phthisis when she arrived in Aiken; her appetite and digestion were very poor, and she was affected with chronic diarrhœa. Emaciation very marked; her complexion of that peculiar pale tint so often met in the advanced stages of consumption. The physical signs present were: extensive dulness over the right lung, with loud, moist râles on both sides, obscuring the other sounds. This patient held her own at Aiken, and subsequently went

to Florida, where she died a few weeks after her arrival.

CASE XIV.—A young girl of fifteen, from Adams, Mass.; Dr. C. W. Burton attending, and Dr. John T. Metcalfe consulting physicians. The disease was ushered in with a copious hemorrhage on March 10, 1878. The bleeding recurred several times, and was followed by fever, remittent in character and tertian in type. In May it was discovered that the right lung was extensively infiltrated. Profuse expectoration now set in and continued until August 1st, at which time she began to show some signs of improvement. This improvement continued until the cold weather of fall necessitated her remaining within doors. Growing somewhat worse, she was sent to Aiken.

December 11, 1878.—The patient, who has improved during the journey, is pale, with bright red spots on either cheek. Pulse, 98; temperature, $98\frac{1}{4}^{\circ}$. Weighs ninety pounds. Catamenia, which had just commenced, have not reappeared since the outbreak of the disease. Expansion of the thorax, which is limited almost exclusively to the left side, two inches. There is dulness over the whole of the right lung; respiration decidedly bronchial, with loud expiratory murmur. Moist râles audible over the whole of the right lung. On the left side the respiratory murmur is exaggerated.

January 9th.—Much improved in appearance; has gained two pounds. Expectoration reduced to half an ounce. A portion of the parasternal region is partially resonant.

February 10th.—Weighs ninety-eight pounds, a gain of eight pounds since her arrival in Aiken. Coughs in the morning and evening only.

March 13th.—Weighs ninety-nine and a half pounds, a total gain of nine and a half pounds. The area of resonance is increasing in extent; a triangular space, with two inches of the sternal and of the clavicle as a base, and the junction of the third rib and sternum as an apex, being quite clear.

April 14th.—Weighs $100\frac{1}{2}$ pounds; making a total increase in weight of ten and a half pounds. The catamenia have returned. The clear triangular space above mentioned has grown larger, the apex being now at the junction of the fifth rib and sternum. She walks several miles without experiencing the least fatigue. The great and steady improvement in this case was as remarkable as it was unexpected; the large extent of diseased surface and the age of the patient having naturally led to the expectation that the result would be anything but favorable.

CASE XV.—A middle-aged mulatto, one of my own patients; first presented himself about eight years ago. He was having quite a profuse hemorrhage from the lungs. The attacks of hæmoptysis continued to recur at longer or shorter intervals. A physical examination afterwards revealed dulness and other signs of infiltration of the right lung. The patient, believing that his hemorrhages were due to malarial poisoning, made repeated applications for life insurance, but was invariably rejected. There has been no return of the bleeding since 1874; the cough has ceased, and the patient's general appearance is that of a person in good health. The only physical signs remaining at this date (June 1st) are slight dulness under the right clavicle and first rib, with some feebleness of the respiratory murmur. The patient's trade is that of a tailor, a fact worthy of note, in a case in which recovery has taken place; that occupation being justly regarded as decidedly conducive to the development of pulmonary phthisis.

So extensive is its prevalence in Vienna among that class of workmen, that it is sometimes designated as "the disease of the tailors."

CASE XVI.—A young man of twenty-three, from New York. Consulting physician, Dr. A. L. Loomis. Mother and brother died of consumption. Disease began in October, 1877, with "cold," followed by fever and emaciation; cough beginning a month later. Has had night-sweats and one slight hemorrhage. Loss of weight, twenty pounds. Color bad. Breathing rapid, with deficient expansion. Pulse, 106; temperature, 102. Dull on the right side from clavicle to fourth rib, and over the greater portion of the scapular region. Respiration bronchial, with moist râles everywhere audible. On the left side, dullness with moist râles. This patient remained a few weeks at Aiken, and then went to Florida, where he afterwards died. During his residence at Aiken there was no material change in the patient's condition.

CASE XVII.—A young lady from Chicago; a patient of Dr. R. P. Lincoln, of New York. The disease in this case began with bronchial catarrh in the autumn of 1875. She came to Aiken for the first time in the winter of 1876-77, with an infiltration of the left lung, extending from the clavicle to the third rib. She improved during the winter, and passed the summer at Faribault, in Minnesota. She returned to Aiken the following winter, and did well, coughing only a little in the morning and evening. The pulse and temperature were normal, and her weight increased from 110 to 113 pounds. In March there was a slight exacerbation of the disease, as indicated by increase in the area of dullness, bronchial respiration, and pleuritic pains on the affected side. This attack was of short duration, and she went North in the spring in good condition. She passed a portion of the summer at Bethlehem, N. H., and then went to Amherst, Mass., where she was laid up with an attack of pelvic cellulitis. This complication, together with the want of proper food, reduced her considerably, and caused her to lose much of the ground she had previously gained. As soon as able to travel she was brought to Aiken.

Dec. 14, 1878.—Notwithstanding the deprivation of her accustomed exercise, her physician having ordered her to maintain the recumbent posture, patient has passed much of her time sitting or lying on the veranda, and there has been a rapid improvement in all her symptoms since her return to Aiken. Pulse, 88; temperature, 99½°. Expansion, 2". Expecto- rates one ounce. The extension of the area of dullness noticed last March is now quite distinct, but that corresponding with the older infiltration has become more resonant. The respiration is bronchial, with prolonged hissing expiration. A few moist râles indistinctly audible under the left scapula.

Jan. 22, 1879.—General appearance good. Lung symptoms much improved.

May 1, 1879.—Much improved. Pulse, 80; temperature, 97½°. Weighs at least 120 pounds, which is above her normal weight. Coughs a little in the morning, raising a few teaspoonfuls of muco-purulent matter. Left side dull from the clavicle to the third rib, but much more resonant than at last examination. Has contracted a slight attack of acute bronchial catarrh, which gives rise to a loud persistent ronchus, which masks the other symptoms elicited by auscultation. In this case, which has been three years under observation, the disease was arrested at least twice, and there was every reason to hope that the good results would have been of a more perma-

nent character, had it not been for the unfortunate complication which for a whole winter deprived her of all exercise in the open air.

CASE XVIII.—A man of thirty-one, a patient of Dr. Santoir, of Brooklyn. Disease began with an attack of pneumonia in July, 1878. Patient's general appearance indicates that he is in the last stages of phthisis; emaciation very great; has lost over thirty pounds; cannot digest food, and vomits continually. Patient grew rapidly weaker, and was removed to Beaufort, S. C., and then to his home in Brooklyn, where he died.

CASE XIX.—Male, twenty-two years; patient of Dr. Chapman, of New Haven. Was taken sick on the 4th of March, with bronchial catarrh. He was at first treated by an irregular practitioner, and lost flesh rapidly. After placing himself under Dr. Chapman's care, there was a marked improvement in all his symptoms.

Dec. 28th.—Color unhealthy; pulse, 120; temperature, 100¾°. Weight, 117½ pounds. Expecto- rates quite a large amount of muco-purulent matter, some of which sinks. Patient has had night-sweats, as well as occasional attacks of hæmoptysis. On the left side there is an area of dullness occupying the whole upper half of the lung, front and back, with bronchial breathing and loud prolonged expiration; crackling mucous râles audible over the whole lung. On the right side no dullness, but prolonged expiratory murmur.

Jan. 1, 1879.—Looks and feels better. Pulse, 108; temperature, 100½°. Expecto- rates less.

Jan. 28th.—The dullness now extends from clavicle to fourth rib and half down the scapula. Weighs 118½ pounds. A gain of three-quarter pound.

Feb. 8th.—Weighs 119½ pounds; a gain of two pounds.

March 23d.—Pulse, 92; temperature, 100°. Weighs more than he has ever done in health.

March 28th.—Cough tighter; is quite hoarse, and has diarrhœa. Pulse, 112; temperature, 101°.

April 10th.—Pulse, 100; temperature, 100°. Has rallied from the late attack, and looks quite ruddy.

April 18th.—Pulse, 92; temperature, 99½°. Weight, 117 pounds; a loss of two and a half pounds.

May 10th.—Pulse, 88; temperature, 99½°. Has had a slight, but persistent, diarrhœa since May 5th.

May 17th.—Pulse, 104; temperature, 100½°. Complains of pain in the left lung, extending through to the back, probably indicative of extension of the disease. Patient has lost four pounds.

May 21st.—Appears to be losing ground; starts for home.

In this case there was marked improvement in all the symptoms, increase in weight, lowering of temperature, lessening of cough and expectoration, until the warm weather of spring caused the attack of diarrhœa, with subsequent extension of the disease and loss of all he had previously gained.

CASE XX.—A middle-aged lady from Norwich, Conn. Had a severe attack of the epidemic influenza, which prevailed so extensively in 1874; has coughed ever since, and in October, 1877, had a copious hemorrhage, followed by loss of flesh, night sweats, etc.

Jan. 4th.—Pulse, 120; temperature, 101; expansion, 2¾" to 3". Suffers in the forenoon with chilly sensations, succeeded by fever. Sweats profusely, and expectorates at least four ounces of muco-purulent matter, all of which is said to float. There is extensive dullness on the right side, extending in front from the clavicle to the fifth rib, and behind, from the supra-spinous fossa to a line corresponding

with the lower third of the scapula. The respiration on that side is bronchial, with abundant mucous râles. On the left side no dulness, but very harsh respiration. The general appearance of the patient is decidedly unfavorable; she is quite weak, and slight exertion produces fatigue.

Jan. 14th.—Pulse, 112; temperature, 98½°. The sweats have ceased, and patient feels stronger.

March 29th.—The condition of the patient during the last two months has remained unchanged; to-day, however, she is much paler, and evidently weaker.

April 14th.—Pulse, 120; temperature, 102¼°. Patient is losing ground.

April 30th.—She leaves for home, her residence at Aiken having prolonged life through the winter, the advanced stage of the disease not admitting of any more favorable result.

CASE XXI.—This patient, a young man from Brooklyn, who had been hitherto attended by an irregular practitioner, was far advanced in consumption; left lung, as well as the larynx, being extensively diseased. Emaciated to the last degree with œdematous swelling of the ankles, it was evident that death would take place at an early date—a prognosis that was verified a few weeks later.

CASE XXII.—An unmarried lady, a patient of Dr. F. L. Knight, of Boston. The disease began with chronic pleuro-pneumonia in December, 1876. On her way South she was exposed to the influence of severe cold in the depot at Philadelphia, which gave rise to severe pain in the chest and a dry, troublesome cough.

March 2d.—Pulse, 112; temperature, 101½°; color, pale. Articulates with great difficulty, being compelled most of the time to speak in a low whisper. Slight dulness under the right scapula, with bronchial respiration.

March 10.—The aphonia has increased; has fever in the afternoon.

March 20.—Pleuritic pains; has less fever, but complains of weariness after slight exertion, and has night-sweats.

April 5th.—General health much improved; laryngeal symptoms as at last examination.

April 28th.—The improvement noted on the 5th has continued; she is stronger, and has increased in weight. No improvement in the laryngeal symptoms, except that the voice is more distinct.

CASE XXIII.—Male, forty-one years old; patient of Dr. Van Bibber, of Baltimore. Hereditary predisposition to consumption on the father's side. Disease began with bronchial catarrh in the autumn of 1877. Has had several attacks of blood-spitting, and suffers with occasional night-sweats. The patient has been some time in Aiken, and is in much better condition than when he arrived, having gained at least five pounds.

March 4th.—Color, good; pulse, 76; temperature, 100°. Dull on left side, between the clavicle and second rib, with bronchial breathing. There are also the same evidences of disease between the scapula and vertebral column of that side.

April 4th.—The patient has continued to improve, having gained three additional pounds during the past month, making a total increase of eight pounds since his arrival in Aiken. There has been no return of the bleeding.

CASE XXIV.—Male, æt. 42; Albany. Has been under the care of a homœopathic practitioner. The lung affection commenced in July, 1870, with an attack of bronchial catarrh followed by hemorrhage

and occasional night-sweats. Passed the winter of 1871 and 1872 at Nassau, and improved there. Stayed at home the following winter, losing ground with the approach of the warm weather of spring, but remaining tolerably well until 1874, from which time until 1876 he passed the winters at home, but came South in the spring. Went to Colorado in 1877, and grew better. Came East in October, and remained in New York until February.

March 5th.—Color, tolerably good; pulse, 96; temperature, 99¾°. Expectorates four ounces of mucopurulent matter in twenty-four hours. Dull on the right side, from the clavicle to the lower border of the fourth rib, with loud amphoric respiration, and other signs of a large superficial cavity. Under right scapula bronchial respiration, with loud, prolonged expiration. On the left side there is no dulness, but the respiration is decidedly bronchial.

March 28th.—Much better; pulse, 84; temperature, 99°. Has gained two pounds.

April 5th.—Goes North much improved in appearance.

CASE XXV.—A young man of 22, a patient of Dr. Calvin Ellis, of Boston. One brother had consumption, but recovered. The disease began with bronchial catarrh in June, 1878. Has had occasional night-sweats and hemorrhages. He came to Aiken in December, but, disappointed because his cough did not disappear as rapidly as he had hoped, he went to Florida. During a hunting expedition in that State he was much exposed, and subjected to great fatigue, which, in connection with insufficient food, and that of bad quality, brought on fever. Growing rapidly worse, he determined, after a short stay on the St. John's, to return to Aiken. It was evident from the fever, the obstinately recurring hemorrhages, and increasing emaciation, that the disease had taken a fresh start. Prior to this date the affection was said to be confined to a limited area in the left lung. He has lost twenty-five pounds.

March 20th.—Over the left apex the percussion sound is short, with very harsh respiration; the expiration being prolonged. On the right side there is a small area of dulness below the clavicle, with prolonged expiratory murmur.

April 23d.—The patient's general symptoms have undergone no material change. The dulness on the right side is now very distinct, extending as low as the third rib.

May 6th.—Patient goes home much worse in every respect. Much of the trouble in this case may be attributed, not so much to his ill-advised removal to Florida, as to his reckless and injudicious mode of life after his arrival there.

CASE XXVI.—A married lady; Drs. Loomis and Nicol, consulting physicians. No history noted.

April 4th.—On the right side there is an area of dulness under the second and third ribs, near the sternum, with bronchial respiration. On the back, same side, there is also dulness under the upper third of the scapula, with increased vocal fremitus. In other respects the respiration presents the same character as in front. Patient complains of circumscribed pleuritic pain over a region corresponding with the area of dulness.

May 3d.—The patient looks quite well; has gained three pounds in weight, and coughs but little. The dulness has disappeared, and the respiratory murmur has lost its bronchial character, being feeble without any prolongation of the expiration.

CASE XXVII.—A married lady from Memphis; Drs. Thornton and Maury. The disease commenced with

an attack of hemoptysis in May, 1877. Has lost eighteen pounds. During the journey the patient was so extremely weak that she had to be carried from one car to another, and even now she is unable to walk across the room without assistance. She was sent to Aiken as a *derrière-ressort*, her friends having regarded her condition as hopeless, and it was feared that she would die on the way. Has had frequent hemorrhages, and the night-sweats have been quite profuse. She had been some weeks in Aiken, and had already gained several pounds.

April 13th.—Very pale, emaciated, with quick and feeble pulse. There is distinct dullness over the upper portion of the left lung.

(The symptoms afforded by auscultation were not noted, but the general appearance of the patient, the dullness on percussion, and the history of the case, are such as to admit of no doubt as to the nature of the disease.)

May 25th.—Patient has had several slight hemorrhages, and has suffered with occasional attacks of pleuritic pain. In other respects her condition is greatly improved.

June 3d.—Has gained six pounds in weight, looks better, and is much stronger, being now able to walk about without assistance. The improvement in this case was as great as it was unexpected.

CASE XXVIII.—A young girl of fifteen, from Cincinnati; Drs. Carson and Richards. Disease commenced with cough on March 7th. Pulse, 96; temperature, 101.

April 17th.—Left side dull in front, from the clavicle to second or third rib; respiration feeble and indistinct in character. On the right side the respiration is louder, with audible expiratory murmur.

April 24th.—Improving; coughs very little, and then only in the morning.

June 8th.—Pulse, 88; temperature, 98½°. Cough has disappeared entirely, and the patient presents all the appearances of a person in perfect health. Notwithstanding her having several sharp attacks of diarrhoea, her weight has increased from 135 to 145½ pounds.

CASE XXIX.—Male, forty years, from Worcester, Mass.; patient of Dr. Calvin Ellis, of Boston, and Dr. Thomas Gage, of Worcester. Began with bronchial catarrh in January, 1879. Has gained three pounds since his arrival in Aiken, thirteen days ago.

April 22d.—Color good; if anything, rather too florid. Expectorates one ounce of muco-purulent matter; pulse, 108; temperature, 101½°. Dull on the right side, from the clavicle to the second rib in front, and as low as the angle of the scapula behind.

April 30th.—Continues to improve; coughs less, and the expectoration is somewhat reduced in quantity.

May 18th.—Patient does not look so well, and there are indications that the disease is extending.

May 22d.—Color bad; is evidently losing ground very rapidly. Area of dullness extends in front to the lower border of the third rib. Patient much worse than when he arrived.

CASE XXX.—A young German from New York, twenty-five years of age. The disease began with bronchial catarrh in 1875, followed by several slight hemorrhages. Spent the summer on Schooley's Mountain, N. J., where he lost his cough and returned to New York, to all appearances quite well. There, by the advice of his physician, an eminent specialist in pulmonary affections, he resumed his business, but was soon again compelled to relinquish it on account of a return of the old symptoms. He was then sent to the

Adirondack region, where he again improved; but finding himself ill on his return to New York, he started for Europe, where he was treated successively at Falkenstein (Dr. Detweiler), at Davos, and at Meran (Dr. Pircher). The patient has passed the whole winter at Aiken, but has done so well that he has not required medical advice. His only object in consulting me is to ascertain to what extent he has improved.

May 13th.—Pulse, 88; temperature, 99¼°. Looks well, and has a good healthy color. Has increased in weight. At all the other resorts he has frequented, the sputa have been more or less tinged with blood; but since his arrival in Aiken there has been no trace of bleeding. He expands the chest to the extent of three inches without any great effort. Dullness quite pronounced under and below the right clavicle; in the axillary line the percussion sound is short. On the back of the same side there is also dullness under the supra-spinous fossa of the scapula. Auscultation reveals bronchial respiration over the left apex, with prolonged expiration in the axillary region. Mucous râles, formerly observed by Dr. Pircher under the upper portion of the scapula, have all disappeared.

CASE XXXI.—A young married lady, patient of Dr. L. Weber, of New York. Disease began in March, 1878. The following letter from her physician will serve as a history of this interesting case:

"Mrs. —, from healthy family, had several slight attacks of bronchial hæmoptæ about ten months ago, during pregnancy. These attacks recurred from time to time, although rarely combined with fever. When I examined her some six months ago, I said to her attending physician that I found on the left side posteriorly unmistakable signs of catarrhal pneumonia of the chronic variety, with tendency to cirrhotic disease of the lung-tissue.

Yours respectfully,

L. WEBER."

126 WEST THIRTY-FOURTH ST.

Jan. 15, 1879.—Patient has lost flesh, her present weight being 121 pounds. In addition to the symptoms mentioned by Dr. W., she complains of occasional attacks of dyspnoea. There is a slight dullness under and to the left angle of the scapula (auscultatory symptoms not noted). Patient has felt much better since she came to Aiken, and the hemorrhages which were previously quite frequent, have only recurred three times since her arrival.

Jan. 19th.—Pulse and temperature normal; no return of the bleeding. The attacks of dyspnoea are much less frequent.

Feb. 10th.—Pulse, 80; temperature, 98½°. The cough, which has been gradually lessening, has now ceased entirely.

April 24th.—Pulse and temperature normal. No return of the cough or of the hemorrhages. Has gained fifteen pounds, and is, to all appearances, perfectly well. Physical examination reveals nothing abnormal, except harsh respiration on the left side.

It will be seen by the table (p. 466), that nineteen out of the thirty-one cases were more or less improved; that in four of these there was entire cessation of cough, the patients being to all appearances quite well when they left Aiken. In five cases the patient neither gained nor lost, or gain in one direction was counterbalanced by loss in another. Of the eight classed as having grown worse, seven had gained in weight and showed other signs of improvement; but, owing to carelessness or ignorance, relapsed. The one case that died was evidently in the very last stage of the disease when he

presented himself for treatment. The results are submitted without further comment to the profession at large; and although chiefly intended for their information, it is hoped that other physicians in charge of the various sanatoria throughout the country may be induced to preserve careful records during the coming season, and conscientiously present for publication the results attained at their stations. It is hoped that those who may be inclined to act on this suggestion, will, if possible, adhere to the plan presented in this paper, and thus enhance the value of their reports when compared with others. It should be remembered that the above report does not include all the cases of consumption that occurred in the writer's practice, but only those which were under observation for periods longer than one month. Quite a large number presented themselves only occasionally, and, not being under continuous treatment, were omitted. A fact worthy of note, and one to which the reader's attention is most earnestly directed, is, that patients wintering at Aiken, as a rule, did better than those which did not arrive until after the warm weather of spring had begun. Another point in the report which should be noted is, that those cases which failed to improve at Aiken were in no way benefited by removal to other resorts.

TABULAR STATEMENT OF CASES OF PHTHISIS TREATED AT AIKEN, SOUTH CAROLINA, DURING THE WINTER OF 1878-79.

Case No.	Lung affected.	Term of residence in Aiken.	Result.	Increase in weight.
I.....	Left.	4 months.	Improved.	Not noted.
II.....	Both.	5 seasons.	Improved.	"
III.....	Both, with cardiac complication.	3 months.	Grew worse.	0
IV.....	Right.	4 months.	Grew worse.	0
V.....	Right.	4 months.	Improved.	9 lbs.
VI.....	Right.	7 months.	Improved.	Not noted.
VII.....	Left.	1 month.	Grew worse.	0
VIII.....	Both.	2 months.	Improved.	Not noted.
IX.....	Both.	3 months.	Unchanged.	"
X.....	Both.	4 months.	Improved.	9½ lbs.
XI.....	Right.	3 months.	Arrest.	3 lbs.
XII.....	Right, with laryngeal complication.	5 years.	Arrest with subsequent relapse.	Not noted.
XIII.....	Right.	6 weeks.	Unchanged.	"
XIV.....	Right.	6 months.	Improved.	10½ lbs.
XV.....	Right.	8 years.	Arrest.	Not noted.
XVI.....	Both.	1 month.	Unchanged.	"
XVII.....	Left.	3 seasons.	Improved.	"
XVIII.....	Both.	1 month.	Grew worse.	0
XIX.....	Left.	5 months.	Unchanged.	Not noted.
XX.....	Right.	4 months.	Grew worse.	0
XXI.....	Left, with laryngeal complication.	3 months.	Died.	0
XXII.....	Right.	2 months.	Unchanged.	Not noted.
XXIII.....	Right.	3 months.	Improved.	8 lbs.
XXIV.....	Left.	2 months.	Improved.	2 lbs.
XXV.....	Both.	6 weeks.	Grew worse.	0
XXVI.....	Right.	1 month.	Improved.	3 lbs.
XXVII.....	Left.	2 months.	Improved.	6 lbs.
XXVIII.....	Left.	2 months.	Arrest.	10½ lbs.
XXIX.....	Right.	1 month.	Grew worse.	0
XXX.....	Right.	4 months.	Improved.	Not noted.
XXXI.....	Left.	3 months.	Arrest.	15 lbs.

A PLEASANT REMEDY FOR TOOTHACHE.—This is found, according to Dr. T. C. Osborn, in the *Medical and Surgical Brief*, in the compound tincture of benzoin. A pledget of lint saturated with the drug and applied to the decayed tooth relieves the pain at once.

Reports of Hospitals.

THE TREATMENT OF TYPHOID FEVER IN THE PHILADELPHIA HOSPITALS.

(Prepared for THE MEDICAL RECORD.)

THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

THE remedies which have been found at the University Hospital to exert the most powerful influence upon the follicular intestinal catarrh, always present in this disease, are first and foremost the nitrate of silver, and next the sub-nitrate of bismuth and carbolic acid. There would seem to be abundant evidence that nitrate of silver reduces the size of the enlarged follicles, relieves the inflammatory engorgement, and allays the hyperaesthesia of the nerves. It has also been settled by numerous experiments that the nitrate of silver is the most easily administered of the three astringents above mentioned, and the best tolerated by the system. If there is any putrid element in the disease, carbolic acid is employed instead of the nitrate of silver. The nitrate of silver is administered in doses of one-fourth of a grain four times a day. This treatment is persevered in until the ulcers have entirely healed.

If the discharge from the bowels is composed of small, semi-solid stools, it is, with propriety, disregarded; but if the stools are watery and large, opium is administered in pill-form, combined with the nitrate of silver. From one-quarter to one grain of the powdered opium is given three times a day. If there is constipation instead of diarrhoea, belladonna is given conjointly with the nitrate of silver.

Great care is had with regard to the diet when the catarrhal inflammation of the intestines is present. The food employed is, of course, as digestible as possible. Milk has been found to be the best diet in this disease. If the curd appears in the stools, the milk is diluted with water, or lime-water. Of this mixture of milk and lime-water three ounces are given every two hours, or a little over two pints in the course of the twenty-four hours. When the bowels are torpid, beef or mutton broth is given alternately with the milk.

The beef-tea employed is prepared after the following recipe: Take a quantity of tender meat, and, after cutting off the fat, chop it up fine, put it in a bowl, pour a pint of water over it, and let it stand over night. The water should be kept just on a simmer—the temperature never being allowed to go above 140°, otherwise all the albumen is coagulated, and so either left on the sieve in straining, or introduced into the stomach in the form of curds. After this simmering solution has been allowed to stand over night, pour it into a pipkin, and heat it again gently with enough salt to give it flavor, and, if necessary, add a drop or two of muriatic acid. Then pour it out over a hair-sieve into a jar. The resulting solution will be found to contain all the nutriment possible, and to be the most valuable kind of stimulant and laxative.

When the fever is high, the patient is given all the food he can take. Care is had, however, that, in allowing food, the already inflamed intestinal tract is not further irritated.

The poison in the blood is controlled by means of quinia, and nitro-muriatic or salicylic acid. As a general thing, salicylic acid is only employed where there is some putrid discharge joined with high

fever. Quinia is considered (1) to neutralize the effects of the septic poison in the blood, (2) to act as a good tonic to the muscular and nervous systems, (3) to tend to check febrile action, and (4) to remove any malarial element that happens to be present. Quinia is never given in the enormous doses advised by the German physicians. It has been found that such doses will break down high fever, but they produce entirely unnecessary irritation of the gastric mucous membrane. About twelve grains of quinia are given in the course of the twenty-four hours.

The temperature is kept down by preventive measures rather than by the cold bath, which is regarded as a last resort. It is unnecessary after this to say that the practice of the University Hospital is wholly opposed to the indiscriminate cold bathing in typhoid fever, so much in vogue in Germany within a year past.

When the temperature runs up in spite of drugs,—in the milder cases, spongings of the whole body are practised every two hours, the sponges being squeezed out of a mixture of water and bay rum at a temperature of from 60° to 80°. If this does not succeed (it rarely fails), and if the patient's temperature mounts up to 104° or 105°, he is then wrapped up in sheets wrung out of cold water. If the temperature still runs up to such an extent that life is threatened, the patient is placed in a cool bath until the bodily temperature is sufficiently reduced.

Before the local lesions appear, the fever can be more boldly attacked; but when, in subsequent stages, it runs high, it is regarded as partaking of the nature of a sympathetic fever, largely dependent upon the amount of intestinal lesion, and the use of baths at this period is thought to be attended with great risk. If the cold bath is used at all (except as a last resort, and when temperature cannot be reduced in any other way), it is employed during the first ten days in cases where the temperature rises above 103° and cannot be controlled by frequent spongings, large doses of quinia, diaphoretics, etc.

With regard to the use of stimulants, the hospital practice is not in favor of administering them simply because a patient has the fever. It is believed that stimulants are only demanded for the relief of certain symptoms. As a general thing, they are not given to children before the age of puberty. They are only administered to old persons, and to meet certain indications, viz., (1) ataxic nervous disturbances, such as sleeplessness, twitchings of the muscles, maniacal delirium; (2) circulatory disturbances, such as feeble and rapid pulse, and feeble development of the first sound of the heart; (3) profound asthenia, as shown by great tremulousness, inability to make any movement, and tendency to slide down off the pillow; (4) dry and brown tongue, with sordes on lips, teeth, and tongue.

The milder forms of stimulants are always used at first. The one most frequently employed is wine-*whewy*. This is made in the proportion of one part of sherry to three of milk, and as much as a gill or half a pint of it is given in the course of three hours. If the symptoms increase, stronger stimulants are used, such as whiskey. Whiskey is usually given in lime-water and milk; the lime-water prevents the coagulation of the milk by the alcohol. These ingredients are mixed in the proportion of one tablespoonful each of whiskey and lime-water to every three ounces of milk. In this form half an ounce of whiskey is given every hour. If the stimulation is doing good, a diminution of the serious symptoms is noted. If the symptoms increase, on the other hand, the amount of stimulus is reduced.

With regard to complications: relapses are always regarded as true second attacks of the disease, and are treated accordingly. The treatment is resumed, the diet restricted, and the same general watchfulness had over the state of the case as during the course of the first attack.

Hemorrhage occurring early in the attack is considered as of but little consequence, but when it supervenes later—when the sloughs are thrown off—it is regarded as a very serious matter. The treatment of hemorrhage is by absolute rest in bed for twenty-four hours, and by the administration of opium, to produce complete quiet for the alimentary canal. The opium is given by the rectum, one grain of the solid opium being prescribed every two or three hours until the patient is gently under its influence; of astringents, for local action, acetate of lead is preferred. A suppository containing one grain of opium and three grains of the acetate of lead is given three or four times daily. Ergot, by reason of its action upon the walls of the arterioles, is also very highly prized. It is given hypodermically near the supposed seat of the hemorrhage. The food allowed is very small in quantity, and absolutely liquid.

Peritonitis is treated by antiphlogistics, sedatives, perfect rest in bed, and a diet which leaves no residuum to irritate the bowels.

True perforation is regarded as beyond the reach of medical skill to mend.

THE GERMAN HOSPITAL.

The quinine treatment (heroic doses) has been given a fair trial in the wards, and has been found to do but very little, if any, good. It has not even been satisfactorily demonstrated that it reduces the temperature, as the same changes in temperature have taken place in the case of those who have been taking the mineral acids alone. Indeed, after giving quinia some time in some cases it was stopped, and the same changes were found to exist. Quinia has seemed rather to increase the diarrhoea and headache, and in two cases it produced entire deafness for two weeks. Sponging with vinegar and water has been found to act beneficially. Plenty of ice is given the patient to suck, and the ice-cap is applied to the head. The wet pack has been found to lower the temperature for the time being, but in an hour or more it generally mounts up again. To this is added the consideration that it has the disadvantage of necessitating the constant moving of the patient, wearing and weakening the constitution, thereby destroying his or her main support against the disease.

Oil of turpentine, as recommended formerly by Dr. George B. Wood, has been proven to act most beneficially. Especially has it been found useful in those cases where the dry, dark, and heavily coated tongue exists, with abdominal symptoms. It is given in twenty-drop doses in mucilage, every hour or two, and is continued in smaller doses during convalescence. In a large number of cases in which dry, dark tongue existed with tympanites, turpentine acted most beneficially, the tongue regaining its normal color and becoming moist in from six to eight days, and the tympanites disappearing in a much shorter time.

The mineral acids are of great service in keeping the stomach in good order, stimulating the appetite and relieving the intense thirst. In many cases the patients call for their dose of the acid hours before the time, so much are they pleased with its taste and effects. The acid commonly used is the dilute nitro-muriatic acid.

Whenever active, wild delirium exists, from one-third to one-half of a grain of morphia is given hypodermically. This medication has been found to act promptly in almost every instance. In one case particularly, the patient towards evening showing signs of approaching delirium, a large dose of morphia was immediately given hypodermically, which had the effect of rendering the patient perfectly rational when he awoke. Upon another occasion, when this same patient again showed signs of approaching delirium, the morphia was omitted, upon which a wild attack of delirium came on, which was at once broken up by the use of a moderate dose of morphia hypodermically.

THE EPISCOPAL HOSPITAL.

The temperature is reduced and the heart strengthened by fifteen-drop doses of the tincture of digitalis and two grains of quinia, every three hours. Stimulants are only employed in the severer cases. Excessive diarrhoea is controlled by injections containing fifteen drops of laudanum and half a fluid ounce of starch. Dilute muriatic acid is given in fifteen-drop doses every three hours, and in the second week of the disease five drops of turpentine are administered every three hours. Hemorrhage from the bowels is controlled by the internal use of ergot, and the local application of ice to the abdomen. A number of cases have been treated of late with one-fourth grain doses of the nitrate of silver in the second week of the disease, this dose being repeated every three hours with entirely negative results.

THE PENNSYLVANIA HOSPITAL.

Ten grains of quinia are given daily, and ten drops of muriatic acid every three hours. The patient is sponged all over with cold water, in the mornings and evenings. Diarrhoea is controlled by opiates and astringents. This is the routine treatment. The diet is very carefully regulated, consisting principally of beef-tea and milk. When the first sound of the heart is altered (weakened) early in the course of the disease, it is regarded as an indication that the patient should immediately be put upon the use of stimulants; or, if he is already taking whiskey, that the daily amount should be doubled.

Progress of Medical Science.

NEUROTOMY OF THE SUPERIOR MAXILLARY NERVE.—In a very interesting paper on this subject published in the *New York Medical Journal*, June, 1879, Dr. F. S. Dennis gives a short *résumé* of the history of neurotomy, and a collection of twenty-one cases of excision of the superior maxillary branch of the trigeminal as far as the foramen rotundum, Meckel's ganglion being extirpated, in a certain number of cases, at the same time. Although too limited to furnish broad and comprehensive deductions, Dr. Dennis believes that these cases will justify the following practical conclusions:

1. The high operation upon the superior maxillary nerve for the cure of neuralgia characterized by pain, having its maximum intensity at the infra-orbital foramen, in the course of the malar branch, and sometimes, although rarely, in the alveolar dental, superior labial, and palatine points, is a better operation than the lower one, inasmuch as these cases show

that the former, as a secondary measure, has cured, or brought relief, in nearly every case in which the latter has failed to do so.

2. The operation is justifiable, as the record shows no case in which death has occurred as an effect of the operation, nor one in which the symptoms have been aggravated.

3. Relief, if only temporary, is a result which justifies the high operation for neuralgia as much as it does the one for the removal of malignant tumors.

4. Want of success is due to failure as regards a correct diagnosis, not only of the cause of the pain, but also of the site of the disease, whether central or peripheral.

5. If the lesion is situated in the terminal nerve plexuses, polyneurotomy, or the resection of several nerves may become necessary. Mononeurotomy should be reserved for those cases in which the irritant involves the trunk of a nerve near its origin.

6. The principal indication for the employment of this bold but safe operation is found in the obstinate persistence of pain, notwithstanding the trial of all milder measures. The prognosis will be most favorable where lesions involving the plexuses or the nerve centres can be excluded.

It is a significant fact that out of the twenty-one cases that have been collected from all the literature on this subject, more than half have been performed by American surgeons.

EVIDENCE OF STILL-BIRTH.—In an article on this subject Dr. S. W. Abbott suggests the probable value of further observations on the relative volumes of the lungs and body as determined by displacement of water. An absolute standard can scarcely be established, but there may be a relative standard which careful observations will demonstrate. The color of a lung which has not respired is brownish-red, resembling that of adult liver. After respiration, Casper describes the existence of bright red circumscribed patches on a dark bluish-red ground color, and he states that the presence of this insular marbling excludes the idea of a fetal condition, and entitles us to assume as certain the fact of the child having lived after its birth. Pulmonary hyperæmia and artificial inflation may modify the color of the lungs of the new-born. Crepitation only appears after respiration. According to the Prussian criminal code, the position of the diaphragm is to be carefully noted; when this does not rise higher than the fifth intercostal space, the child has breathed; when no respiration has taken place it rises as high as the fourth intercostal space. Air does not enter the middle ear in less than twelve hours after birth. According to Casper the presence in the lower epiphysis of the femur of an osseous nucleus of three Rhénish lines (about six millimetres) in diameter, permits the deduction that the child has lived after its birth, but the converse of the rule does not hold good.—*The Boston Medical and Surgical Journal*, August 28, 1879.

CHANGES IN THE MEDICAL FACULTY OF YALE COLLEGE.—At a meeting of the Yale corporation on October 22d, Dr. William H. Carmalt, for several years a lecturer in the Medical School, was appointed a full Professor of Ophthalmology and Otolaryngology. Dr. Francis Bacon was invited to resume duty as Professor of Surgery, and the following lecturers were appointed: Dr. W. O. Ayres, of New Haven, on Diseases of the Nervous System; Dr. S. H. Chapin, of this city, on Diseases of the Throat, and Dr. Matthew D. Mann, of Hartford, Clinical Lecturer on Gynecology.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, November 15, 1879.

LEGAL LIABILITIES OF HOSPITALS AND OF MEDICAL MEN.

A RECENT decision by the Supreme Court of Rhode Island will have considerable interest to the medical profession, and especially to those members of it who are connected with charity hospitals. It appears that a man in Providence, R. I., while working in a lumber-yard, had two of his fingers cut off by a circular saw. He was taken to the Rhode Island Hospital, and there put under the care of the interne. Ether was administered, and attempts were made to stop the bleeding. This could only be done, however, by the application of the tourniquet, and that instrument was kept on for seventeen hours. The result was, that eventually the arm had to be amputated at the shoulder-joint. When the patient recovered he sued the hospital for damages on account of unskilful treatment, and because the interne did not summon the visiting surgeon in accordance with the hospital rules.

In the court the judge directed the jury to give a verdict for the defendant, on the ground that an institution supported as this was, by public charity, should not be made liable for negligence or unskilful treatment. The knowledge that there was such a liability might deter the benevolent from giving money to such institutions. The case was appealed, however, and this judgment reversed.

In his decision the judge stated that hospital corporations should be considered liable for failure to exercise reasonable care in selecting skilful, competent men as internes, and that they were also liable for negligence on the part of the internes in carrying out the proper rules of the institutions, such as sending for the visiting surgeon in cases of emergency.

This decision is stated by the *Sun* to be justified by legal authorities, although contrary to the decisions of some other courts in like cases.

Looking at the matter from the medical stand-

point, it appears to us that, on the whole, this recent decision will be endorsed by the profession as a just and salutary one. There can be no doubt that instances of carelessness and negligence on the part of hospital internes are not very infrequent, although as a rule these young men perform their duties with great faithfulness. The fact that the hospital corporation is responsible for their acts will tend to make it more particular in its selections, and to lessen the weight of personal and political influence, which has so great a share in the appointments.

In suits against doctors personally, however, we have always advocated the greatest lenity on the part of the court. It is usually very difficult for the non-professional mind to appreciate the complexities that may surround even a simple case, and the fact is notorious that it is an immense injury to a physician to be sued for malpractice, even if he gets a verdict in his favor. It should be well understood that courts of law will not often grant damages in such cases. This is but justice to the doctor who, if a genuine one, will never allow any injury or inattention to ensue from such a state of affairs. Let the corporations be watched, but the doctor have a little balance in his favor. He has a hard enough time apart from courts of law.

INSTRUMENTS OF PRECISION.

THE ingenuity of medical men has been displaying an unwonted activity of late, and new methods and appliances for the examination of the human body are being continually announced. Instruments of precision just now are in the ascendant; and never before have anatomical structures or physiological functions been put under such close and exact scrutiny.

We learn that electrical lights are penetrating the viscera, and that the pathological changes in the blood-corpuscles are being very exactly noted and classified. The news of these things has already reached the laity. It is announced in a leading New York daily, that a celebrated microscopist has allowed a gentleman to marry because his white blood-corpuscles were—or were not—finely granular. In fact, there have been so many other interesting reports of this kind that we find it well to call attention to some of these devices with which humanity is becoming so closely environed.

We have spoken in a previous issue of the apparatus that has been invented by a French physiologist for measuring the amount of heat thrown off from the body in any given time. If we may believe the inventor, the temperature changes of our systems can now be put under the exactest supervision; a man can neither change his diet nor undergo a physical exertion without it being registered in British units. With the present delicate surface thermometers also, only local changes in nutritive activity can be determined. Active cerebration, an over-loaded stomach,

or a deep-seated inflammation, all send up the index. To a lively imagination the practical application of these various forms of thermometry promises the most extraordinary results in the cerebral department. When it is established, as it is hoped it may be, that the value of a thought is to be measured by the amount of cerebral tissue consumed and heat evolved, every man's intellectual calibre can be definitely established in degrees Fahrenheit; the problems of life will then be greatly simplified.

There has always been much ingenuity shown in investigating the normal and pathological conditions of the lungs, but never before have investigations presented such large, we may say sonorous, results. Mr. Edison, for instance, promises us a stethoscope, with which we hope nothing less than that the breeze from the epithelial cilie may be heard and differentiated, as also that the noise from the development of a tubercle may be brought with melancholy distinctness to the ear. These are but hopes and promises, however, which may partially fail us. We take pleasure, therefore, in recording the more modest, but better established inventions of a gentleman from New Jersey; inventions which deserve notice, indeed, if only for the melody of their nomenclature. There is, first, the Respiratory Anemometer. This instrument consists simply of a tube, a valve, a movable pen, some gearing, a few levers, a strip of paper, and clock-work. By breathing into the tube, a record is obtained of the character of the respiration, with the relative length of inspiration and expiration.

Supplementary to this valuable piece of mechanism are the Pneumasyren and the Unison Resonator. The former gives, among other things, the character of the respiration, while the latter announces to the ear the smallest deposit of tubercle. With these three instruments, a stethoscope, a pleximeter, and a sounding towel, it will be strange, indeed, if phthisis cannot be arrested even in the third stage.

Dr. Richardson, of London, has utilized the microphone in such a way as to form what he calls an audiometer. By it the capacity of the ear to appreciate sounds can be accurately measured, and he has already made some interesting discoveries in regard to hearing. The application of the carbon telephone to urethral surgery is well known. Sir Henry Thompson, by attaching a form of this instrument to a Mallechort rod, finds that the presence in the bladder of the smallest particle of gravel even is readily appreciated. It only remains to extend its application to the pelvis of the kidney. Some time ago Dr. Nestler, of Germany, announced that he had invented an endoscope, with which he could see the interior of the bladder, and even of the stomach. At the recent meeting of the International Medical Congress, M. Trouvé, of Paris, stated that with his electrical polyscopes he could accomplish this same result, and an exhibition of his instruments was

made. Thus the glory, as well as the necessity, of Alexis St. Martin is taken away.

We have referred to but a small part of recent mechanical achievements, but it is enough to show that the medical profession is progressing, and is, as usual, absorbing the other sciences into its own. The present inventive tendencies, of which, perhaps, we have spoken too lightly, show the impress which modern physics is making on medical science, and we would by no means undervalue its benefits when within the scope of practical utility.

ANNUAL REPORT OF THE SURGEON-GENERAL OF THE ARMY.

The annual report of Surgeon-General Barnes shows that there were 21,000 white, and 1,942 colored troops in the army during the past year. The number of cases of sickness among the troops was about 42,000; the number of deaths about 670. The number of medical officers is 326, of whom 150 are acting assistant-surgeons. The amount of sickness and death among the colored troops appears to be much greater than among the whites. The number of cases of sickness is proportionately very large, since 42,000 cases among 23,000 soldiers would oblige each soldier to be sick twice during the year. The ratio of sickness to mortality is also very much greater than that among ordinary communities. Usually there is one death to every twenty-five or thirty cases of illness; in the army, however, there is apparently only one death to every sixty-two cases of sickness. These apparent discrepancies, however, are due to the peculiar method of compiling the statistics. Thus: a sick call is held every day, and all those applying for treatment on that day, unless sent to the hospital, are enumerated as new cases. In this way, a man may have a mild but chronic affection, calling for daily treatment, and be counted in as a new case each time he is seen by the surgeon.

This method of dealing with the figures has probably certain advantages, or it would not be adhered to; but it is liable to give a wrong impression as to amount of sickness in the army.

NEW TYPE FOR MEDICAL RECORD.

The present issue of the RECORD appears with a new dress of type. We are excusable for congratulating ourselves on the fact, especially when we speak on behalf of our readers. As we considered it was not too early to begin a good deed, we resolved not to wait for the commencement of the next volume before making the change.

DEATH OF M. CHASSAIGNAC.—M. Chassaingnac, to whom surgery is indebted for the introduction of the drainage tube into practice, died on August 26th. He had, for some time, retired from active life.

Reviews and Notices of Books.

I. THE LAWS OF THERAPEUTICS; or, the Science and Art of Medicine. By JAMES KIDD, M.D. Philadelphia: Lindsay & Blackiston, 1879, pp. 196.

II. THE GROUNDS OF A HOMŒOPATH'S FAITH. Three Lectures delivered at the request of Matriculates of the Department of Medicine and Surgery (Old School) of the University of Michigan. By SAMUEL A. JONES, M.D., Professor of Materia Medica, etc., in the Homœopathic Medical College of the University of Michigan. Philadelphia and New York: Boericke & Tafel, pp. 92.

I.—Dr. Kidd is a physician in London enjoying a large practice among the upper classes. He happens to be the medical attendant of the Earl of Beaconsfield, and during the late Berlin conference was summoned thither to attend his illustrious patient. The homœopaths of London were quite jubilant at the honor thus paid to one of their own guild.

The London *Lancet*, with its proverbial acuteness, cruelly discomfited the enemy by declaring that Dr. Kidd was not that sort of a man, but, on the contrary, one "who repudiates the description attributed to him, and who by no means avowedly pursues the method of Hahnemann in his treatment." After both sides have had their say, Dr. Kidd, in the volume before us, speaks for himself. He first discusses the historical aspects of his subject, then devotes a few chapters to physiology, pathology, the natural history of disease, and the general subject of therapeutics. The three following chapters are devoted to "Hahnemann's law of similars," to "Galen's law—the antipathic," and to a comparison between the two. In these three chapters we find the author's bias clearly expressed in favor of the former law. The rest of the book is devoted to other subsidiary matters. The apparent object of the book is to give prominence to the homœopathic idea, and we fear our contemporary the *Lancet* was a little at fault in its assertions concerning the author's "treatment." If a preference for the doctrine of "similia" does not constitute a homœopath in the ordinary acceptance of the term, we are at a loss to know what does. In justice to Dr. Kidd, however, it should be stated that he does not confine himself to homœopathy, but, when in a tight place, freely roams through the whole domain of medical science in search of remedial agencies. We are aware that it is the habit in Paris for the same medical publishers to issue both regular and homœopathic works. It now appears that this custom has taken root in Philadelphia.

II.—Much complaint has been made that the medical faculty of the University of Michigan lecture to homœopathic students, and thereby perhaps save some of them from becoming irregulars. It would appear, however, from the title-page of the work before us, that the tables had been turned, and that a homœopathic professor was lecturing to the regular students in the hope of seducing some of them from the paths of rectitude and (medical) virtue. Certainly, affairs are decidedly mixed in Michigan. But jesting aside—the author gives us a new definition, or rather mark of distinction, between the homœopathic physician and "his older brother in the science and art of medicine." The characteristic of the former, he says, is "not the law of cure, not the Hahnemannian hypothesis of chronic diseases; none of these, but simply this—his fixed faith in the efficiency of drugs." He then goes on to explain the nature of homœopathy, and more especially Hahnemann's connection with it,

indulging by the way in a good deal of pathos (we had almost written bathos). The writer wields a ready pen, and evidently believes that rhetoric may perhaps persuade, where logic fails to convince. His second lecture is devoted to a witty criticism of a rather extreme instance of polypharmacy, and advocates the use of a single drug at a time—that is to say, if the physician wishes to learn anything about the effects of the medicine he is using. This is all very well, but we fear that there are some physicians whose main desire is to cure their patients, and who are perfectly willing that somebody else should do the experimenting. It is not given to every one to be a "Dr." Carver, and we presume that for many years the shot-gun will be preferred to the rifle. There is, however, a good deal to be said on both sides of this question. In the third lecture the author advocates the use of the small dose. His argument on the whole matter may be briefly summed up in a few words: if the law of similars be true, the single remedy and the minimum dose are the logical and practical sequences. A good deal, however, depends on the *if*, and we can hardly accept the conclusions until the hypothetical is replaced by the positive. On the whole, the subject is presented in a less objectionable manner than is common with writers of his school. The book is interesting—in parts amusing.

ASTHMA; ITS PATHOLOGY AND TREATMENT. By J. B. BERKART, M.D., Member of Royal College of Physicians of London, etc., etc. London: J. & A. Churchill, 1878.

This agreeably written treatise upon an intractable disease is well worthy of possession. The cases with which the work abounds are effectively related, and well represent the views of the author. The objective symptoms justly demand a larger share of the reader's attention, and by an inevitable logic almost wholly separate the complaint from the usually accepted class of purely nervous affections. Every phase of organic lesion is duly considered, and we arise from the perusal of this monograph with a feeling that there have been satisfactory additions to our knowledge.

Reports of Societies.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Annual Meeting, October 27, 1879.

DR. A. E. M. PURDY, VICE-PRESIDENT, IN THE CHAIR.

The Society was called to order at 8.15 p.m., and the minutes of the last stated meeting were read by the Secretary, Dr. F. A. Castle. The Secretary then read the report of the Comitia Minora for the entire year, ending with the final meeting of the committee, held October 22, 1879.

The Treasurer then read his report, which showed a balance in the treasury of \$1,257.70.

The election of officers being next in order, the Vice-President appointed Drs. H. T. Hanks and H. B. Conrad tellers. The result of the election has been published.

REPORT OF THE COMMITTEE ON HYGIENE.

Dr. J. C. PETERS, Chairman of the Committee on Hygiene, read extensively from a voluminous report,

made up largely of material furnished by Dr. Roger S. Tracy and Dr. E. G. Janeway. The streets, the sewers, the drains, the privies, and the water-closets of the city, the noises made by the elevated railroad, street cars, carts, and other vehicles, the docks, the fumes arising from manufactories, and the Fourth avenue tunnel nuisance, were subjected to criticism.

The portion of the report relating to the health of the city showed a mortality from all causes during the nine months of 1879, ending with September, of 21,867 against, in round numbers, 26,000 in 1878, 24,000 in 1877, and an average for the first nine months of a series of years from 1878 back to 1871, inclusive, of 22,516.

There had been an unusual number of deaths from small-pox, although the disease had not prevailed epidemically. During the last nine months 39,574 vaccinations had been performed by the corps of the Board of Health under the direction of Dr. Taylor. Bovine virus had been employed exclusively.

The mortality from typhoid fever had been much less than in previous years. During the nine months of 1879 only 122 deaths had occurred from this disease against 156 in 1878, 179 in 1877, 207 in 1876, 251 in 1875, and an average for the first nine months of a series of years from 1878 to 1871, inclusive, of 201. The same notable diminution in the mortality from the severer forms of typhus was reported.

It was argued by Dr. Janeway that, from these figures, the stringent sanitary control exercised by the Board of Health over the tenement-houses and the tenement-house population of the city was beginning to be felt in decreased rates of mortality from preventable causes.

The mortality from measles had been comparatively small.

The mortality from whooping-cough had been comparatively large, showing a total of 466 for 1879.

The mortality from scarlet fever had been the largest it had been since 1860, the aggregate number of deaths having reached 1,370, against 741 in 1878, 781 in 1877, and 1,278 in 1860. The disease had not at any time during the past nine months prevailed epidemically.

The mortality from diphtheria had been less than for any corresponding nine months since 1872, showing a total of 453.

The mortality from croup had been less than two-thirds the usual average.

Diarrheal diseases had been steadily decreasing in number since 1876, when a mortality of 3,060 occurred, against 2,084 for 1879. The diminution was ascribed chiefly to the work of the special visiting corps of physicians appointed by the Board of Health for the summer months.

On motion, the report was accepted, ordered upon the minutes, and the Secretary directed to forward a copy to the Chairman of the Committee on Hygiene of the Medical Society of the State.

REPORT OF THE COMMITTEE ON ETHICS.

DR. F. V. WHITE, Secretary of the Committee on Ethics, read a brief report in which the Society was congratulated that its ethical health was much better than last year. In 1878 there were 175 cases, and in 1879, 22 cases for adjudication. Ethical questions had not absorbed the time of the Society and prevented it from contributing to the diffusion of true science, particularly to a knowledge of the healing art.

The report was accepted, and ordered to be placed upon the minutes.

REPORT OF COMMITTEE ON PRIZE ESSAYS.

DR. FORDYCE BARKER, Chairman of the Committee on Prize Essays, made the following report, awarding the prize to an essay written on "Affections of the Ear arising from Diseases of the Teeth," and bearing the motto: "Ore Audi":

"This essay is worthy of award from its careful study and appreciation of the physiological relations of the organs discussed, its original suggestions relative to their pathological associations, the clinical facts which seem to have been intelligently and honestly reported, its simplicity, lucidity, and correctness in style, its value as a contribution to practical medicine on an important class of affections which, as bearing any relations as cause and effect, has hitherto received but slight attention from medical writers."

On opening the envelope bearing the motto, Dr. Barker found the name of Dr. Samuel Sexton, of New York, to whom the prize was awarded.

Worthy mention was made of an essay "On a Simple Polarizing Apparatus and its Application to Practical Medicine."

The report was received, and ordered to be placed on the minutes.

REPORT OF THE CENSORS.

DR. H. G. PIFFARD, Secretary of the Board of Censors, read the report, in which was shown the Society's lack of legal power to take action with reference to certain cases of violation of the code. The functions of the board were of a three-fold character: 1. Those which pertain to them as members of the Board of Censors as established by law; 2. Those that are immediately incumbent on them by one of the sections of the system of medical ethics; and, 3. Those which devolve on them as members of the Comitia Minora, according to the by-laws of this Society. Under these heads the report was continued at some length, and then accepted and ordered upon the minutes.

REPORT ON AID FOR YELLOW-FEVER SUFFERERS.

DR. JOHN C. PETERS, chairman of the committee appointed to solicit aid for the families of physicians who died of yellow fever during the prevalence of that disease in the South in the year 1878, reported that the committee had received \$4,998.10, and distributed \$3,700, leaving in hand \$1,298.10. The number of physicians who died during the epidemic of 1878 was 101.

ANNUAL APPROPRIATION.

On motion, the sum of \$1,500 was placed at the disposal of the Comitia Minora, subject to the approval of the Society, with which to carry on the work of the Society for the ensuing year.

MISCELLANEOUS BUSINESS.

Under the head of Miscellaneous Business, a communication was read that had been sent by Dr. Wm. A. Hammond, calling attention to a statement in the published minutes of the Stated Meeting for September, in which the claim was made that Dr. John S. Billings founded the National Medical Library. Not in any way desiring to detract from all credit due to Dr. Billings, he wished to correct the statement made in the published minutes by saying that, while Surgeon-General, he founded this library several years before Dr. Billings was stationed at the city of Washington.

The communication was accepted, and ordered to be placed on the minutes.

REVISION OF THE PHARMACOPOEIA.

A resolution offered by Dr. Piffard was adopted, requesting the medical colleges of New York City to appoint their full quota of delegates to attend the next convention, to be held for the revision of the U. S. Pharmacopœia, and protect the interests of physicians.

APPROPRIATION FOR THE TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE.

DR. PIFFARD offered a resolution to the effect that no appropriation should be made for the publication of the scientific Transactions of the Medical Society of the State of New York, but that they be authorized to contribute toward the publication of its business proceedings, to the end that the same shall be given a wider circulation.

On motion, the resolution was referred to the Comitia Minora.

On a resolution presented by Dr. Piffard, the Comitia Minora was instructed to appropriate a sum not exceeding \$250 for the services of the Secretary for the ensuing year.

The Society then adjourned, to meet on the fourth Monday in November, 1879, at 8 P.M.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 8, 1879.

DR. JOSEPH W. HOWE, VICE-PRESIDENT, IN THE CHAIR.

SUPPURATIVE PHLEBITIS—THORACENTESIS.

DR. J. LEWIS SMITH presented a specimen of suppurative pleuritis removed from an infant who died in one of the public institutions. The history of the case was as follows:

Frank, aged about eighteen months, and having ten teeth, entered the New York Infant Asylum, Aug. 9, 1879. His previous history was not ascertained, except that he had been feverish and fretful during the preceding three or four days. The following record of his state was made on the evening of the 9th: "A light, moist fur upon the tongue; has had one thin and greenish stool during the day; no vomiting; urine high-colored; has an occasional cough, apparently without much pain; frets when pressure is made on lateral portions of chest and abdomen; axillary temp., 104½°; fauces slightly red. There is marked dullness on percussion over entire right side of chest, but not so great in the mammary and infra-clavicular regions as posteriorly. Fine, moist râles are heard when the ear is applied over the lower angle of the right scapula, and coarser moist râles in the anterior portion of right lung. Brandy, quinine, and the usual poultice—one part of mustard to sixteen of flaxseed—were ordered, as also one teaspoonful every second hour of beef, wine, and iron.

August 10th.—Respiration as before; dullness, amounting to flatness on percussion, over entire right lung, except a little resonance in infra-clavicular and mammary regions; no fremitus is observed below the angle of the scapula when the baby moans or cries; axillary temperature, 102½°. Diagnosis: pleurisy, with effusion.

August 11th.—Pulse frequent, but not weak; frets much, and has at times the expiratory moan; but the cough is loose, and apparently with little pain; axillary temperature, 102°; otherwise, symptoms and physical signs as before, and the same treatment is continued. Evening; continues to have an occasional

expiratory moan; is thirsty and fretful; apex beat of heart in *linea mammalis*; pulse, 130; resp., 60; a distant vesicular murmur is noticed below the scapula on right side; bronchial respiratory murmur above the spine of scapula; the coarse râles previously noticed, which may have been moist, pleuritic sounds, have nearly ceased; flat percussion-sound, and absence of fremitus as before; since yesterday, at one examination, percussion over the mammary region gave tympanitic resonance, but now the sound is flat; no bulging of intercostal spaces; measurements of the two sides of the chest have been several times made, but the difference, if any, is slight.

The records state: Aug. 12th, temp., 101¼°; pulse, 120; resp., 54. Evening: tympanitic resonance again observed over right mammary region; otherwise, no notable change in symptoms and physical signs.

13th.—Temp. 103¼°; pulse, 160; resp., 80; coughs but little; moans occasionally. 6 P.M.: temp., 103, resp., 76; pulse, 144. On the 14th and 15th little change occurred, the symptoms and physical signs remaining as before. The axillary temperature on the morning of the 14th was 101¼°; resp., 80; pulse, 140. Evening: temp., 104°; pulse, 160; resp., 88. 15th: morning temp., 103¼°; pulse, 140; resp., 84.

On or about August 15th the point of the hypodermic needle was introduced into the chest, about one inch below the lower angle of the scapula, but with no result; and, several days later it was again introduced two-thirds its length, without touching the liquid. On subsequent examination little change was noticed, either in symptoms or physical signs, except that, on August 20th, the records state that there was tympanitic resonance on percussion over both the infra-clavicular and mammary regions, while there was flat percussion-sound posteriorly; bronchophony was present in the scapular region, and the respiratory murmur observed when the ear was placed over the scapular and infra-scapular regions was indistinctly vesicular, or broncho-vesicular. Everything possible was done to sustain the vital powers; but during the month of September the patient gradually lost ground, becoming by degrees weaker and more wasted, and the febrile movement continued of a hectic character.

On Sept. 18th the axillary temperature was 101°, and the lymphatic glands of the neck were observed to be prominent. Death occurred October 2d, from exhaustion.

Autopsy on Oct. 3d: Is much wasted; abdominal organs apparently healthy; the liver extends two inches below the ribs; a few old pleuritic bands unite the anterior surface of the left lung to the ribs; this lung healthy, but not fully inflated; the anterior surface of the right lung is united to the ribs by adhesions firm but somewhat elongated; posteriorly over this lung is a purulent exudation extending from one inch above the base to within one inch of apex; vertical diameter of purulent collection about two and a half inches; lateral diameter about two inches. It is walled in anteriorly by the lung; posteriorly, by the costal pleura, which is nearly one line thick, and is easily detached from the ribs; and laterally, by adhesions. This abscess, therefore, extends over the posterior surface of the upper and lower lobes, and slightly over the middle lobe; the liquor puris has been mostly absorbed, so that the contents of the abscess, which have a pulsatious consistence, are composed mainly of the débris of the cell-walls and nuclei of pus-corpuscles; very few unbroken cells can be discovered by the microscope, but the mass consists mainly of granular matter with

shiny, oily particles resulting from granulo-fatty degeneration and destruction of the cells; the entire amount of purulent matter is not more than one ounce, probably less; lung underneath the pus apparently somewhat compressed, but healthy; mucous membrane of air-passages also healthy; an abscess in the right side of the neck, resulting from the adenitis and cellulitis, contains about two teaspoonfuls of pus; moderate hyperplasia, without cheesy degeneration of bronchial and mesenteric glands.

There are several facts of interest in this case. One was the difficulty of diagnosis. The differential diagnosis of pleurisy with effusion, and pneumonia in infancy, is often very difficult; for those signs which we rely on, as indicating the presence of a liquid in adult cases, are, for the most part, absent, or feebly marked in the infant, even when the amount of liquid is large. In the pleurisy of the infant we may notice, when the ear is applied over the affected side, bronchial respiration, broncho-vesicular or vesicular, for all these modifications of respiratory sound are transmitted through the liquid, either from the lung on the affected side, or from the healthy lung of the opposite side, since the small amount of liquid in infantile cases does not present a barrier to the transmission of sound, as in adult cases. The pleurisy in the above case being on the right side, the important sign of displacement of the heart was lacking, which is commonly present in infants as well as adults when the effusion is on the left side. Repeated measurements showed no notable difference in the two sides. The slight difference noticed in the examinations varied so much that we were in doubt whether there was any actual difference in the dimensions, the tape being carried from the middle of the sternum to the spine a little below the nipple.

I was led to diagnose pleurisy, contrary to the opinion of other good observers, from the fact that there was such extensive flatness on percussion developed in so short a time—the percussion-sound of pneumonia being dull, but not flat; from the absence of fremitus when the hand was placed over the infra-scapular region; and from the character of the respiratory sounds, which were not so distinct, and were more distant than in cases of pneumonia. Nevertheless, there was no bulging of the intercostal spaces; and, according to my experience, there frequently is none in the pleuritic effusions of infancy, even when the quantity of liquid is quite large. Why the hypodermic needle did not touch the pus I am unable to say. Subsequently, the persistence of the symptoms, especially of the fever, confirmed the diagnosis. The profession have learnt in recent years that pleurisy with effusion is not uncommon in infancy and childhood, and that it is often suppurative in those who are cachectic—as after scarlet fever—and in foundlings. It is seldom that an epidemic of scarlet fever occurs in New York, that I do not meet cases of empyema as a sequel of this exanthem, and almost every year cases of idiopathic empyema occur among the children in our asylums.

DR. SMITH remarked that he had sometimes observed fremitus in undoubted cases of pleuritic effusion, and that in some cases he was able to explain its occurrence as follows: The lung became attached by pleuritic adhesions to some part of the parietes of the chest, against which it was more or less compressed. This gives rise to similar anatomical conditions for the production of fremitus, as in pneumonia; namely, a solid lung lying against the ribs. Thus, in one case in which fremitus was observed along the side, and upon the front aspect of the

chest, the subsequent autopsy showed the presence of adhesions at these points. There is another interesting fact as regards the pleuritic effusions of young and feeble children. They are prone to atelectasis, and the liquid meeting therefore less resistance on the side of the lungs than of the ribs, compresses the lungs, while, as stated above, it produces little effect in pressing outward the intercostal spaces and the ribs.

DR. VAN GIESEN referred to a case of pleurisy which progressed from its inception to the post-mortem without cough.

THE DIAGNOSIS OF PLEURISY FROM PNEUMONIA.

DR. JANEWAY remarked that there was usually great difficulty in diagnosing pleurisy from pneumonia. Some authors believed that the presence or absence of vocal fremitus would settle the question. He had met, however, with vocal fremitus in pleurisy, and found it absent in pneumonia. He recalled two cases of empyema in which there was flatness along the inter-lobar line, bronchial breathing, bronchophony, and exaggerated vocal fremitus over the flat region. An hypodermic needle was introduced both times, but no fluid was discovered. There was a still more doubtful series of cases, in which, at the outbreak of empyema, you get crepitation in the line of the axilla, followed by bronchial breathing, bronchophony, and flatness. Here were the physical signs of pneumonia, with nothing more to help the diagnosis than the protracted course of the disease and the occurrence of hectic fever.

In using the hypodermic needle upon the chest, he had often failed to get fluid when fluid actually existed in the pleural cavity. He believed that the failures could be explained in several ways. The suction of the syringe might not be perfect, a piece of false membrane might be pushed in front of the needle, or a flake of exudation might surround the point, or the point of the needle might enter an adherent portion of the lung. He generally used a veterinary hypodermic syringe for the purpose, as the aperture was larger and less apt to become clogged.

DR. SMITH had frequently met with cases of empyema in which the lung was adherent at different points. In the latter situations he had detected vocal fremitus.

DR. JANEWAY had met with such adhesions in which vocal fremitus was not present, while, on the other hand, he had found fremitus over a space in which fluid was imprisoned in a tight sac.

CONCERNING A FREE OPENING IN EMPYEMA.

DR. SMITH remarked that an interesting point arose in reference to the treatment of empyema when it was known to exist. Of course it was proper to let out the pus. But how, was sometimes the question. He had a case in private practice of empyema after scarlet fever, and had been aspirating the chest for six weeks, at intervals of seven or eight days. The case had not progressed well, and he was inclined to think that a free opening would be preferable.

DR. POST was in favor of making a free opening in such cases, and of allowing it to remain.

DR. JANEWAY thought it was well to try aspiration once or twice, with a view of diminishing the size of the cavity; but, failing in the latter attempt, it was then advisable to make a free and permanent opening.

DR. POST had noticed that, in cases of empyema,

especially in children, there was very rapid improvement after free evacuation.

Dr. LEALE referred to a case he had treated in 1865. The patient was a man from whose chest he had removed seventy-two ounces of pus, and there was no reappearance, the recovery being perfect. He also alluded to the case of a child, aged two years, from which sixteen ounces were evacuated at one aspiration. The chest opening was closed hermetically, according to Howard's plan. There was no re-formation of the pus, and the child made a perfect recovery. He also alluded to cases in which the pus reaccumulated after aspiration, and where it was necessary to establish free drainage. Whenever the openings became closed, hectic fever resulted.

Dr. SMITH wished, in that connection, to refer to a point in reference to the diagnosis of these cases. In the adult it was well known that aid in diagnosis was given by measurement. Not much, if any, assistance was given by such a method of procedure in children. Especially was this the case in weakly subjects who had oedema after scarlet fever. Such children were very prone to atelectasis; and when pus accumulated in the pleural cavity, the lung was compressed rather than the ribs thrown out. He believed that, in the majority of such cases, there was not much difference in the measurement of the two sides. In one instance the circumference on the affected side was less than that on the other.

Dr. WYLER stated that it was the practice of König, a German surgeon, to remove a section of the rib one and a half centimetres long, when the intercostal spaces were too narrow to allow free drainage. König then used a three-per-cent. solution of carbolic acid as an injection.

Dr. ROBINSON believed that there were only two signs that enabled any one to diagnose pleurisy, viz., absolute dulness, and absolute absence of respiratory murmur.

Dr. JANEWAY relied a great deal upon the distant respiratory sound in pleurisy with effusion.

(To be continued.)

Correspondence.

LITHOTRITY WITH EVACUATION OF FRAGMENTS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In your editorial of August 16, 1879, page 159 of the RECORD, on "Lithotripsy with Evacuation of the Fragments—Part I. The Development and Principles of the Operation," it is stated that "he (Prof. Bigelow) saw the fact, recognized it, and promptly made use of it. The fact was the tolerance of the bladder to the use of instruments within it. . . . Many lithotritists went beyond the three-minute rule, but they did it only occasionally and, as it were, under protest; . . . yet no one, until Prof. Bigelow, drew what seems now such a palpable inference. Sir Henry Thompson claims that he did so; but, so far as we can judge, he did no more than many others; that is, he departed, in exceptional cases, from the rule of short sittings; but it was only a drift, and was very different from Prof. Bigelow's sudden recognition of a principle of general application." And further on, "he (Prof. Bigelow) had then enunciated the principle; he had put lithotripsy upon a new basis; he had *fait école*."

Some twelve or thirteen years ago, my friend, Prof. E. M. Moore, of Rochester, gave me his conception of an ideal operation of lithotripsy, by which the stone was to be seized, crushed, and entirely removed from the bladder at a single sitting. Prof. Moore spent much time upon an instrument devised for this purpose, and, it seems to me, recognized the fundamental principle of Bigelow's operation, namely, "the tolerance of the bladder to the use of instruments within it." As evidence of this, I refer to Prof. Moore's article, "A New Method of Lithotripsy," read before the American Medical Association in 1870, and published in Vol. XXI. of Transactions, at page 251.

I beg leave to quote briefly from this article, page 251: "I have long been convinced that lithotripsy cannot be a successful rival of lithotomy until its processes can be finished at the same sitting that commences them. This implies a period of time short enough to be tolerated. Lithotomy is a violent proceeding." . . . Page 252: "But the severe handling in lithotomy receives its compensation in the fact that the foreign body is absolutely removed, and the process of repair is begun with no cause of interference. . . . Lithotripsy is usually but the withdrawal of half the splinter, and converting the remaining half into a sort of chevaux-de-frise, bristling at all points. The period of time that seems allowable in lithotritic handling is limited by Erichsen to ten minutes. Thompson prefers five. If every particle were removed, I cannot but believe that much more may be allowed. Probably thirty minutes could be borne quite as well as in the ordinary condition subsequent to a sitting."

Then follows a description of the instrument, and a report of a case in which it was used, with the statement on page 254 that "my plan proposes a sort of reversal of all the methods of lithotripsy; to hold the stone gently, and not crush; to rub down, not break; to wash away at once, and not allow the fragments to be rounded by time and attrition, as preparatory to their evacuation."

On account of pressure of professional labor and lack of skilled workmen, Prof. Moore did not complete his instrument in all its details; but it seems evident, on reading his paper, that he had drawn the "palpable inference," and made "the recognition of a principle of general application," on which the success of Dr. Bigelow's operation depends.

Very respectfully yours,

WILLIAM S. ELY.

ROCHESTER, N. Y., Oct. 29, 1879.

PHARMACOPŒJAL REMEDIES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—It is generally expected that regular physicians will use the remedies or formulæ of the Pharmacopœia as far as they will readily meet the wants of patients; and especially in preference to secret and advertised medicines. But how often is this neglected, even among the Nestors of the profession—those whom we delight to admire and honor. In a late work on clinical medicine by a standard authority, for constipation we find recommended Lady Webster's dinner-pills, *Grains de Santé*, Tamar Indian, and other like remedies, as if the Pharmacopœia did not afford equally good and even better laxatives. The so-called Lady Webster pill is that of aloes and mastic of the U. S. P., which was not suggested by Lady Webster, but merely preferred by her. The formula is nearly as old as that of the aloes and

myrrh pill, or pil. rufi, which is nearly two hundred years old. The object of the mastic is to retard the solution of the aloes in the small intestine, and thereby cause it to act upon the large bowel. The pill is a good one, but should not be called Lady Webster's, at least by physicians, for that leads to the belief that Lady Webster was a better prescriber than the doctor.

The recommendation of the *Grains de Santé* is in still worse taste. They are composed of aloes and jalap, and are very carelessly made indeed, and apparently not of the best materials. The combination seems a strange one, but is an excellent one, when both the small and large bowels are to be acted upon. One grain of extract of socratine aloes and one of resin of jalap makes an active pill for most persons; one grain of the former and two of the latter is far more powerful in its action than most persons would suppose. They can be supplied by apothecaries, either silvered or sugar-coated, and made of purer articles at a less price than the imported imperfect pills. Tamar Indien is apparently composed of resin of jalap in fig-paste; they are very expensive indeed. The Friedrichshall, Pullna, and Hunyadi waters are little more than solutions of epsom and glauher salts, and should not be prescribed for poor persons at least, as their chemical composition is well known, and a prescription can easily be given for these inexpensive articles, with great saving to persons in moderate circumstances.

PHARMACOPEIA.

CAUSE OF SUDDEN DEATH IN THORACENTESIS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Dr. M. P. Jacobi's note upon this subject, with the replies to it, were perused with interest in view of a case I desire to report as evidence corroborative of Dr. Robinson's statement, that pain of the puncture *par et simple* may be the cause of a reflex impression upon the nervous system and heart sufficiently overwhelming to induce death. The case is as follows: W. Bronson; farmer; married; æt. 43. Left pleural cavity completely filled with effusion; heart beating some three inches to right of right border of sternum. Cervical veins turgid. Great dyspnoea. Had been sick four months. Aspiration was attempted. The act of puncturing gave him no pain, but a few minutes after the needle was introduced he began to complain of pain in the region of the wound. It was also diffused over that side of the thorax. Moving the needle did not increase it greatly. One gallon of serum was withdrawn without, apparently, any excessive diminution of the contents of the cavity. Not a single unfavorable symptom save the pain was experienced. Four weeks later the effusion, in spite of treatment, being as great as before, aspiration was again essayed. From the minute after the needle was inserted he complained of pain, which in a short time became most intense. Allowing the needle to rest quietly, by intermitting the aspiration a hypodermic of morphia was given. After a sufficient time, this not sufficing, the needle was withdrawn, reintroduced, and aspiration proceeded with. About fourteen ounces of fluid had been *very slowly* taken out, his complaints steadily increasing, when a most alarming collapse came on, which only, by the utmost exertions, was prevented from proving fatal. The suffering continued for several hours. A third time, one week later, I again attempted aspiration, the cavity as tense as before; this time preceding, by a hypodermic of

morphia a sufficiently long time for its effects to be thoroughly felt, the introduction of the needle. Less than one ounce had been withdrawn, he complaining a little, when a most overwhelming—I can describe it in no other way—attack of pain supervened, and the same collapse came on, which once more seemed likely to prove fatal. Aspiration was not again attempted.

In this case the pain alone was the sole cause of the collapse. In the first operation, where he had very little pain and such a large quantity of fluid was taken away, not a single unfavorable symptom made its appearance. In the second operation, where the pain was most intense, it caused a nearly fatal prostration. The small quantity of fluid removed forbids any other assumption. The effect the last time, where every precaution was taken, is confirmatory of this; for less than one ounce had been aspirated when the same alarming symptoms supervened.

Respectfully,

G. E. GOODFELLOW, M.D.

ELECTRICITY A PARALYZING AGENT.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The article under the above heading, by Dr. Poole, published in No. 18 of the MEDICAL RECORD, scarcely requires any refutation. To every one acquainted with electro-physiology a few quotations from it will be sufficient to prove the fallacy of the author's theory. For instance, he says:

"It is important here to note, as negative evidence of the truth of our proposition, that Prof. Trowbridge, of Harvard College, *has demonstrated* (italics ours) that the supposed natural currents of electricity, believed by Matteucci and Du Bois-Reymond to be present in nerve and muscle in repose, do not exist," etc.

"Nor is electricity known to be generated at all in the bodies of men and animals, since even in the case of certain electric fishes, which display a remarkable use of this agent, the electricity which they discharge may be simply induced in them by the opposite electricity of the media surrounding them," etc.

"In view of the present state of knowledge on this subject, those who assert that natural electricity plays any part in the vital operations of the living organism, will have to begin anew the task of eliciting evidence in support of that doctrine."

"We assert that electricity is a paralyzer of nerve-tissue, and we claim that *all the effects it produces* (italics ours), as employed for therapeutical and physiological purposes, may be readily accounted for on this view of its action."

"We shall appeal to the recognized authorities themselves in support of our thesis," etc.

Fortunately the time for speculating and theorizing, which had so long retarded the progress of medicine, has passed away, and facts based on experimental researches have now to be given in support of every assumption. The existence of inherent currents in the muscles and nerves, discovered already by Galvani, was demonstrated half a century later with most exact scientific methods by Du Bois-Reymond,* and the elucidation of the laws of the electrical phenomena in muscles and nerves constitutes now one of the best chapters of physiology—the muscle and nerve physics. Hermann† attempted to attack this

* E. Du Bois-Reymond: Untersuchungen über thierische Electricität. Berlin, 1848 and 1849.

† L. Hermann: Weitere Untersuchungen zur Physiologie der Muskeln und Nerven. Berlin, 1867.

theory with arguments far more striking than those brought forward by the author of the article, but they only served to establish on a still firmer basis the whole doctrine of animal electricity.*

As regards the paralyzing hypothesis of electricity, one experiment with the galvanoscopic frog-preparation will prove its absurdity.

By stimulating the sciatic nerve with a very weak induced current, scarcely any muscular contraction is produced; but if we pass through the nerve an ascending galvanic current and then stimulate it as before (in its catelectrotic region) with the same induced current, a powerful and prolonged contraction—tetanus—will follow. The author of the paper would explain these phenomena by paralysis of the nerve causing the contraction of the liberated muscle. If we now reverse the direction of the polarizing current, and again stimulate the nerve with the same induced current and at the same point as before (now anelectrotic region), no contraction can be called forth even with the most powerful current. Or, instead of reversing the electrotonizing current, we simply stimulate the nerve above it, and thus produce the most powerful tetanus, while by stimulating the nerve below the electrotonizing current, no contractions are produced, however strong may be the stimulating current. We may repeat this experiment indefinitely, and shall always obtain the same result—either tetanus or a complete absence of contractions, according to the direction of the polarizing current. If, then, the author considers the contraction a consequence of the paralysis of the nerve induced by the current, he must admit that the absence of contractions is the result of an opposite, *i. e.*, tonic condition of the nerve, although induced by the same current. Therefore, according to his own theory, under certain conditions the electric current produces in the nerve a condition entirely reverse to paralysis assumed by him. Should the author object (in accordance with his theory) to the stimulation by electricity, the same result may be obtained by applying a chemical stimulus (solution of common salt), or even by a mechanical stimulus. Any one acquainted with Pflüger's *Physiologie des Electrotonus* will find it easy to give similar illustrations.

The author has conceived an erroneous theory, because he has *not* "appealed to the recognized authorities" in electro-physiology. He was evidently impressed by the reasonings of some eminent physicians (Rudcliff, Russell Reynolds, Anstie, and others), whose merits are certainly unquestionable in matters of practical medicine, whereas in electro-physiology the classical researches of Du Bois-Reymond, Pflüger, Bernstein, and some others, have to be taken as a guide.

WM. B. NEFTEL.

Obituary.

OLIVER WHITE, M.D.,

NEW YORK.

DR. OLIVER WHITE died Nov. 7th, at his residence in this city, of cardiac disease, aged 69 years. He was born in the town of Somers, N. Y., a few miles from this city, April 9, 1810. By descent Dr. White belonged to one of the oldest and most distinguished families in New England. His great-great-grand-

father was Rev. Ebenezer White, the lineal descendant of Judge Thomas White, of Weymouth, Mass., who was a member of the Colonial Court in 1636, and figures with honor in the musty colonial records of that time. Dr. White's great-grandfather was the Rev. S. White, but his grandfather appears to have rebelled against the traditions of the elders, and to have insisted upon studying medicine in preference to theology, and appears in the local annals as Dr. Ebenezer White. His son, Ebenezer White, Jr., followed in the footsteps of his father, and was a physician of high local repute in Somers and the adjacent towns. Oliver White, son of the latter, pursued his first medical studies in his father's office, but subsequently entered the medical department of Yale College, where he was graduated doctor of medicine in 1831, being at that date 21 years old. He was licensed to practise by the State Medical Society of Connecticut during the same year, and at once entered upon active practice, removing to this city for that purpose. In 1836 he was elected a member of the Medical Society of the County of New York, and served both as President and as Vice-President of that organization. About that time there was a great deal of professional controversy, bickering, and division among medical practitioners in this city, and it was in the midst of this state of things that a few young practitioners, Dr. Willard Parker, Dr. White, and others united in the formation of that now venerable institution, the Academy of Medicine, of the original Fellows of which Dr. White was one of the few survivors, having served it in the capacity of Vice-President. He was also one of the founders of the Society for the Relief of the Widows and Orphans of Medical Men—indeed, one of its principal promoters, having been at different times its President and Vice-President, and for over twenty years one of its active managers. He was a member of the American Medical Association and of the State Medical Society, to whose "Transactions for 1864" he contributed a valuable memoir entitled, "Impalement through the Vagina, with Recovery." Dr. White has been for years one of the consulting physicians of the Presbyterian Hospital and the President of its Medical Board, serving at the same time upon the consulting staff of the Northeastern Dispensary and as a Trustee of the New York Dispensary. He received the honorary degree of M.D. from Bellevue Hospital Medical College in 1875. Dr. White leaves a considerable fortune, but no direct heirs. His widow survives him. The funeral services took place at one o'clock, p.m., Nov. 10th, at the First Presbyterian Church, Fifth avenue and Twelfth street, of which he was an active and valued member. The New York Academy of Medicine and the Medical Society of the County of New York, and other Societies of which the deceased was a member, attended the services.

ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 24 to November 8th, 1879.

SUTHERLAND, CHAS., Col. and Surgeon. Having reported at Division Headquarters as Medical Director of the Division, is assigned to duty at the Presidio of San Francisco, Cal., from this date. S. O. 130, Div. of the Pacific and Dept. of California. Oct. 24, 1879.

MENN, C. E., Capt. and Asst. Surgeon. To take post at Fort Hays, Kan., and after reporting there, to

* E. Du Bois-Reymond: *Gesammelte Abhandlungen zur allgemeinen Muskel und Nerven Physik.* Berlin, 1877, p. 319.

proceed to Fort Garland, Col., and report to Col. McKenzie, 4th Cavalry, for duty with the column now organizing there. S. O. 217, Dept. of the Missouri, Oct. 30, 1879.

HOFF, J. V. R., 1st Lieut. and Asst. Surgeon. When relieved by Asst. Surgeon Shufeldt, to comply with orders from A. G. O. in his ease. S. O. 98, C. S., Dept. of the Platte.

SHUFELDT, R. M., 1st Lieut. and Asst. Surgeon. Relieved from duty at Fort Laramie, and assigned to duty as Post Surgeon at Fort Fetterman, Wyo. T. S. O. 98, Dept. of the Platte, Oct. 29, 1879.

APPEL, D. M., 1st Lieut. and Asst. Surgeon. Relieved from duty at Fort Stanton, and assigned to duty at Fort Bayard, New Mex., as Post Surgeon. S. O., 109, Dist. of New Mex., Oct. 31, 1879.

APPEL, A. H., 1st Lieut. and Asst. Surgeon. Assignment to duty at Fort Bennett revoked, and to repair to Fort Pembina, Dak. T., and report to the comdg. officer for duty as Post Surgeon. S. O. 118, Dept. of Dakota, Oct. 27, 1879.

Changes in the Medical Corps of the Navy during the week ending Nov. 7, 1879.

BOGERT, E. S., Surgeon, and M. D. JONES, Pd. Asst. Surgeon, detached from the U. S. S. Monongahela, and wait orders.

WAGGENER, J. R., Pd. Asst. Surgeon, detached from the New York School Ship St. Mary's, and ordered to the Receiving Ship, Boston.

DEANE, C. W., Asst. Surgeon, detached from the Receiving Ship, Boston, and wait orders.

ROSS, JNO. W., Pd. Asst. Surgeon, detached from duty with the National Board of Health, and ordered to the School Ship St. Mary's.

LIPPINCOTT, GEO. C., Pd. Asst. Surgeon, detached from the Navy Yard, New York, and ordered to special duty, Bureau of Medicine and Surgery.

NOURSE, C. J., Asst. Surgeon, detached from the Receiving Ship, Norfolk, and ordered to U. S. S. Tallapoosa, temporarily.

ANDERSON, F., Pd. Asst. Surgeon, ordered to the Navy Yard, New York.

GARDNER, J. E., Asst. Surgeon, ordered to the Receiving Ship Franklin, Norfolk, Va.

THE PLAN FOR A NATIONAL PUBLIC HEALTH ASSOCIATION.—The following circular explains itself:—

NATIONAL BOARD OF HEALTH,
WASHINGTON, D. C., Nov. 1, 1879.

To the Sanitarians of the United States:

By the act establishing the National Board of Health it is made the duty of the board to report to Congress at its next session a plan for a national public health organization, which plan shall be prepared after consultation with the principal sanitary organizations and the sanitarians of the several States of the United States, special attention being given to the subject of quarantine, both maritime and inland, and especially as to regulations which should be established between State or local systems of quarantine and a national quarantine system.

In order to fulfil this requirement, the National Board of Health has requested those interested in the subject to communicate their views to the board, and now respectfully invites members of State and local boards of health and sanitarians generally to meet with it in conference in the city of Nashville, Tenn., on the 18th to 23d November meeting of the American Public Health Association.

J. L. CABELL,
President National Board of Health.

T. J. TURNER,
Secretary National Board of Health.

THE CHINESE IDEA OF DIET.—Dr. Dauphin W. Osgood, Surgeon to the Foochow Medical Missionary Hospital, Foochow, China, in his interesting report just published, says:

"The Chinese usually inquire 'What shall I eat?' and if we would gain their confidence, it is well to give them careful dietetic directions, as the native doctors rarely neglect to give minute instruction in regard to food.

"I take a few directions from the 'Golden Mirror,' a native work compiled by order of the Emperor Chien Lung, relating to diet. It is said that horse-flesh may be eaten, if care is taken to avoid the part that has been covered by the saddle.

"The liver must not be eaten, as it will cause death, unless the eater avails himself of the following receipt, which is published in the above mentioned work:

"B. Take the excrement of a male rat, pulverize and dissolve it, and take internally as required.

"A white horse with a black head, if eaten, will cause insanity. Women who are pregnant are required to abstain from eating turtles, chickens, and ducks, for fear that their offspring will be deaf and dumb. It is to be feared that the child will have hare-lip if the mother eats rabbits.

"Pears are said to cause the ague, and onions, if eaten in the first month, will cause skin diseases.

"Nearly all kinds of food are divided into three general classes, viz., hot, cold, and medium. Medicines are similarly divided with the addition of two or three extra divisions. Diseases are also classed as hot and cold.

"The Chinese are gradually learning to use western medicines, and the demand for them will doubtless increase. The sales for the most part have been quinine, fr. iron, carbolic acid, and santonine. The receipts from sales have amounted to \$76.77. There is occasional inquiry for medical books. Dr. Hobson's works are somewhat behind the time, having been printed twenty years or more, but are liked by the Chinese. Dr. Kerr has done good service by translating a work upon chemistry, and is preparing a work upon materia medica, also one upon skin dis-

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 8, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Nov. 1, 1879....	0	13	41	1	66	32	0	0
Nov. 8, 1879....	0	12	36	1	64	40	1	0

THE YELLOW FEVER.—The number of deaths that occurred from yellow fever in the city of Memphis for the week ending November 8th, was eight. No new cases have been reported within ten days.

eases. A good work upon anatomy, well illustrated, is a great desideratum in China. This might be effected by a few of the medical missionaries dividing the work, and then submitting their several translations to a committee for final revision before publication."

PROF. JAMES AITKEN MEIGS of Jefferson Medical College, Philadelphia, died Nov. 9, aged 50 years. An obituary notice will appear in our next issue.

TREATMENT OF DIPHTHERIA.—Dr. F. A. Hubbard, Taunton, Mass., writes:—

In numerous cases of diphtheria I have found the following of great use:

B. Sodii hyposulphitis,
Potasse chloratis, āā..... ʒ i.
Aq. cinnamomi..... ʒ iv-viii.

M.

A more convenient form is:

R. Sod. hyposul.,
Potass. chlo., āā..... ʒ ss.
Ol. cinnam..... gtt. x.

M.

This mixture may be dissolved in water as required.

The solution may be used as a gargle, taken internally, or applied as a spray. With its use the fetor is reduced to little or nothing, and improvement is usually rapid. In connection with this, I have used small quantities of "Tully's powder," with quinine, brandy, and other supporting measures, as required in each case.

Externally, over the swollen glands, hot fomentations or camphorated oil with a flannel bandage.

If there is dyspnoea from extension of membrane downward into the bronchi, the vapor of lime slaking in hot water. A coffee-pot is useful here, for the most unwilling can be made to inhale the steam as it escapes from the spout. However, when the lungs are attacked, treatment is of little account. At the outset of the disease I usually give a mild aperient.

FACULTY OF THE UNIVERSITY OF MARYLAND.—The following changes have been made in this Faculty. Prof. Frank Donaldson has resigned the chair of Physiology and Hygiene, and will occupy the chair of Clinical Professor of Diseases of the Throat and Chest. Prof. F. T. Miles will fill the chairs of Physiology and Anatomy, in addition to his duty as Clinical Professor of Diseases of the Nervous System.

THE COMMITMENT OF PERSONS TO HOSPITALS FOR THE INSANE.—Dr. Isaac Ray delivered a very interesting lecture on this subject before the Philadelphia Social Science Association at the College of Physicians in that city, on Thursday evening, October 23d. Dr. Ray began by remarking that just precisely what legislation is required, touching this subject, is one of the vexed problems of social science. In the sudden and violent forms of insanity the patient is placed under strict surveillance, his wishes are disregarded, etc., and yet this is justified by common sense and by the common feeling of mankind. Nobody would question the right of a man to confine his wife to the house if she were bent upon self-destruction or abused her children. But being in institutions, they can be better treated than at home, and it would seem natural to make choice of them for the confinement of patients. The matter is regulated by an act of Assembly passed in 1869, which requires the sanction of two physicians. It is alleged that physicians may be biased by their relations to

the family, by false representations, or make mistakes, and by some it is proposed to make the confinement of the insane the subject of a legal investigation, to be conducted by some magistrate, judge, or commissions appointed for the purpose. If there is to be an inquisition, who so competent to make it as medical men, when it could be so done without unnecessary trouble or publicity. It may be that the liberty of any person in the community is at the mercy of the physician, but so is the life of any one who is ill. In signing the certificate of insanity the physician performs a professional service, and is responsible to the laws of his country. If the matter were supervised by a judge or magistrate, owing to the stress of other duties, it would become a mere matter of form. It is not improbable that persons are detained in confinement who never were insane, or kept confined after they have recovered. Where this is supposed to be the case, friends should be called and made to show cause why the patient should not be detained; the matter should be advertised, and the investigation of each case occupy at least two days. To hurry through an insane asylum once or twice a year and listen to all the tales told would not be enough. Proper judicial investigation is what the public demands. The officers and physicians of our hospitals and institutions have no interest in detaining a patient. Their salaries are the same in either alternative. The safeguards already established are sufficient for the purpose; but at the same time it is advisable that there should be a supervisory board established, which should be directly responsible to the government. The act of 1869, however, provides that application can be made to the judges, and any person can be brought before them and have a hearing upon a writ of *habeas corpus* at the request of a respectable citizen. The speaker then referred at some length to the pauper insane supported at the public expense, and thought that they should have the benefit of hospital treatment, and that towns and cities should be compelled to send their paupers, who could not be comfortable elsewhere, to hospitals, and also that people should not be allowed to keep insane persons at home in confinement.

LARYNGEAL PHTHISIS.—The mooted question in regard to the pathogeny of this affection has received some additional light through the labors of Heinze, of Leipsic. This author cites 475 cases which were examined in the dead-house. He found the larynx ulcerated in 30.6 per cent. of all the cases, and the intestines in 51.3 per cent. The disease was oftenest found between the ages of 21 and 30. There were tubercles in the larynx or trachea, or both, in 94 per cent. of the cases. The author concludes: first, that primary tuberculosis of the larynx is not proven; second, that it is impossible to tell positively whether an ulcer is tubercular without an examination of the lungs, although a very probable diagnosis may be made by the help of the laryngoscope; third, a cure of laryngeal tuberculosis will, most probably, never be made.—*St. Louis Clinical Record*.

INCREASE OF CONSUMPTION IN SOUTHERN LATITUDES.—Attention has heretofore been called to the fact that there has been a steady increase of deaths from phthisis among the natives of the Madeira Islands, and in Naples, Florida, and other health resorts. It now appears that the same thing is happening in New Orleans, and the mortality has recently been so great that attention has been called to the fact by the local press. During the first week in August, the

mortality from consumption in New Orleans was twenty-four, which at the same rate throughout the year would be an excess of that from all fevers combined. It is thought that the increase is only in part due to the visitors coming south for their health.—*Phila. Med. and Surg. Reporter.*

EDITORIAL CHANGES.—The editorial management of the *Canada Medical and Surgical Journal* has changed hands. Dr. Fenwick, who has edited the journal for the past fifteen years, has resigned, and his place has been taken by Drs. Geo. Ross and W. A. Molson. The recent numbers keep up its reputation for a well-conducted journal.

MEDICAL COLLEGE OF OHIO.—Dr. Jas. G. Hyndman, by unanimous vote of the trustees, has been appointed Lecturer on Medical Chemistry at the Medical College of Ohio. Dr. Hyndman has been associate editor of the *Cincinnati Lancet and Clinic*, and during this time has been connected with the college laboratories in various departments.

THE WAY IT WAS DONE IN LOUISVILLE.—Under this heading the editor of the *Medical Herald* charges a distinguished New York oculist with highly unprofessional conduct. It is stated that for two months prior to September 25th, the local press published announcements at intervals, to the effect that the gentleman referred to would visit Louisville, and would see patients at 2 o'clock every day from Sept. 25th to Oct. 1st, at the office of a friend and former pupil. With the said announcements were the statements that the New York doctor was the greatest oculist, as well as hygienist in the world. He arrived, and received patients as it was said that he would. Notwithstanding the *Herald's* belief to the contrary, it seems so unlikely that the doctor knew anything of, or had anything to do with the newspaper publications, that we refrain from giving any names.

INDIANA, ILLINOIS, AND KENTUCKY TRI-STATE MEDICAL SOCIETY.—This Society met at Evansville, November 4th, 5th, 6th, and 7th. The annual address was delivered by the President, Dr. J. A. Ireland. Public addresses were made by Dr. J. M. Keller, of Louisville, and by Dr. E. H. Gregory, of St. Louis. A large number of papers were presented.

FROZEN MEDICINE.—It is asserted by Dr. Edwin Andrew that many drugs can be given with superior advantage by first freezing them. Antiseptic, astringent, anti-emetic, and nauseous medicines come under this head, and can be combined with ice without difficulty. An especially good feature of this plan is in its affording a possibility of the stomach's retaining medicines which it would reject when given in ordinary ways.

HOMŒOPATHY IN CAMDEN COUNTY, N. J.—The regular profession in Camden County, New Jersey, has been very much exercised of late.

Some time ago, the county erected an insane asylum, and appointed a committee to manage it. This committee, not being well posted in medical matters, suddenly appointed a homœopath as superintendent of it. This, of course, isolated the institution from all the benefits of regular medical skill, and from all the great insane asylums of the United States. After a six months' trial, the experiment was decided to be a failure, and a regular physician was placed in charge. The homœopath, who is said to have been a person of more than average ability, stated to the board in his defence, that he had administered the homœopathic treatment "similia similibus curantur"

to a person with epilepsy, until the patient became so bad that he had a thousand fits in six weeks. Then, by resorting to regular doses of chloroform and ice to the spine, the fits were stopped.—*Phila. Med. Times.*

A NEW VEGETABLE PEPSINE.—Dr. Bouchut, of Paris, created much interest at the recent International Medical Congress by exhibiting a new vegetable pepsine, obtained by himself and Prof. Wurtz from the papaya of Java and South America. This new substance, which is called papavine, possesses all the digestive properties of animal pepsine, making very short work of a piece of beefsteak.

The power which the papaya plant has of making meat tender has long been utilized by the inhabitants of Java, and has heretofore been discussed in medical journals. To Dr. Bouchut, however, belongs the credit of furnishing us with precise knowledge on the subject, and of extracting the active principle.—*Louisville Med. News.*

CARE OF THE INSANE.—The necessity of giving more room to the insane is becoming appreciated in Pennsylvania at least. The private insane asylum at Kellyville has recently been enlarged; and, at the Pennsylvania Hospital for the Insane, another ward is now building, not for the purpose of receiving more patients, but in order to furnish more room for the present occupants.—*Phila. Med. Times.*

Original Lectures.

CLINICAL LECTURE ON MELANCHOLIA :

BEING THE SECOND OF A COURSE OF FOUR CLINICAL LECTURES UPON THE DIAGNOSIS OF INSANITY, DELIVERED UNDER THE AUSPICES OF THE COMMISSIONERS OF CHARITIES AND CORRECTION, AT THE NEW YORK CITY ASYLUM, WARD'S ISLAND, BY THE MEDICAL SUPERINTENDENT,

A. E. MACDONALD, M.D.,

NEW YORK.

MELANCHOLIA.

GENTLEMEN:—The patients whom I present to you to-day illustrate the second of the four forms in our classification of insanity—the form of melancholia. You will readily perceive that there is a very decided difference between them and those whom we saw at our last meeting—at once in their appearance, their attitude, and their conduct. We have now the asthenic as opposed to the sthenic form of insanity, depression taking the place of excitement. There is none of the liveliness which was before apparent in action and speech, and instead there is depression both of mind and body. In the former class the patient was drawn out of himself, was keenly alive to all that was said and done about him; now he is self-absorbed, his thoughts are turned inward, and he is too much concerned in the contemplation of his own griefs and sufferings to pay much attention to his surroundings. If he regards them at all, it is only because he sees in them fresh dangers or new impositions.

We are accustomed to speak of melancholia, as of mania, as either acute or chronic, sometimes taking account of the arbitrary division based upon the duration of the disease, but oftener, and more properly, having regard to the general type of the symptoms presented. Another division, depending upon the manifestations in the individual patient, recognizes the two forms—melancholia with frenzy and melancholia with stupor—in accordance with the approach toward mania on the one hand, or dementia on the other. It must be remembered that the clean-cut differences in the forms of insanity which we can draw in our descriptions, or illustrate by the selection of typical patients, do not obtain through all clinical cases; that there is a gradual approach of the different forms toward one another; and that we will often find patients so exactly upon the border-line between mania and melancholia with frenzy on the one side, or between dementia and melancholia with stupor on the other, that it is hard to tell just how to class them.

ESSENTIAL DIFFERENCE BETWEEN MELANCHOLIA AND MANIA.

Whatever the particular form which melancholia may assume, the essential difference between it and mania is, as I have said, the element of depression both physical and mental. We have now pallid face, feeble circulation, arrested secretions. The approach of melancholia is slower than is that of mania. There is no sudden and unexpected outburst, but the period of alteration is longer and is more likely to be appreciated by the friends of the patient, or even by himself. In fact, it is by no means uncom-

mon for the patient to recognize the approach of his malady, to detect the want of reason in his fancies, and to endeavor to argue and steel himself against them, and perhaps for a time with success.

PROMINENT SYMPTOMS.

Sleeplessness is the first prominent symptom in this as in other forms of insanity; disturbance of the emotions follows; and positive delusions soon assert themselves. The patient is unable to apply himself to his former pursuits; he becomes fretful and ill-natured, his natural affections are blunted and soon transformed into actual suspicion and dislike of his family and friends, and into the firm belief that they are conspiring to do him injury, and this feeling is apt to go on to the production of violence either toward himself, or, in what appears to him self-defence, toward others, unless the plain indications in such a case are followed, and he is removed from his customary surroundings and associations.

PHYSICAL CHARACTERISTICS OF MELANCHOLIA.

The first case which I present to you shows plainly, as you see, the physical characteristics of melancholia, and in a very acute form. Indeed, this is but the fifth day of his asylum residence, and his admission followed very closely upon the recognition of his disease. He is much emaciated, feeble in movement and in voice, and his face wears the expression of great mental suffering. He shows you the banner, the carrying of which through the streets and into the churches led to his arrest; and he explains the reason of the inscription upon it. The inscription is, "Freemasons everywhere!—among women and children!—all working cautiously!—Guard children everywhere!" and the explanation is that, ascribing all his own troubles, real and imaginary, to the body named, he considers it his duty to give this warning to others.

SUPPOSED INFLUENCE OF SECRET SOCIETIES UPON THE INSANE.

It is remarkable how frequently the false ideas of the insane are based upon the supposed influence of secret societies upon them. And it is a practical point worth remembering, for it may lead to the detection of evidences of insanity in examinations, where, if the subject is not broached, the patient may not reveal his delusions. There are two or three channels, indeed, in which the delusions of melancholia are apt to run, and in my own examinations I am accustomed to lead the conversation to the subjects of freemasonry, spiritualism, witchcraft, and electricity, with a pretty fair certainty that in connection with one or other of them the insanity will be revealed, if it exists.

You see that the patient does not seek to argue in support of his belief as to the influence that has affected him; nor does he cite any manifestations by which he has detected the influence. He *knows* that the Freemasons are responsible for his troubles, and that is enough for him.

CHRONIC MELANCHOLIA.

The second patient is an older man than the first, and his disease is of longer duration and more chronic in character. He has an equally troubled expression of countenance; but he is better nourished, and is, indeed, in very fair physical health—and by this the chronic condition of his malady and the slight prospect of recovery are indicated, for, when a patient improves in bodily condition without a parallel improvement in mind, it is a very discouraging sign.

You see that the patient's throat presents the cicatrix of an extensive wound, and he tells you that he tried to kill himself just before coming to the asylum. This is the history of many other patients, and I can hardly recall a case of melancholia in which the patient recovered sufficiently to describe his own feelings, where he did not give an account, if not, indeed, of an actual attempt at suicide, at least of a very decided impulse in that direction.

SUICIDAL ATTEMPT.

This is the danger in melancholia as opposed to mania—of injury to the patient himself rather than to others; of the latter there is comparatively little fear. Patients suffering from melancholia with frenzy, do sometimes make attacks upon others, but the motive differs from that which actuates the maniac. In the one case it is fear, in the other anger. The former acts in self-defence, as it were. In endeavoring to escape from the dangers which beset him he attacks those who try to restrain him; or his sufferings become so intense that he turns upon the person whom he believes responsible for them.

But the main danger is that of suicide, and the tendency toward it is so general and so pertinacious, that it cannot be too carefully guarded against. The attempts at self-destruction do not always occur from the same motive. In the present instance the man tells us that he tried to kill himself because he thought others were trying to kill him; and, singularly enough, this most illogical reason is the one oftenest assigned. But in other cases the suicide is attempted or committed because the patient is so disheartened by his imaginary troubles or diseases that he despairs of escape or cure; or it may come from delusion, or from hallucination, as, for instance, where the act is committed in obedience to the voice of the Deity, which the patient imagines that he hears. A peculiarity which it is important to remember is, that there is often not simply a disposition to self-destruction in any possible way that may present itself, but to self-destruction in a definite and particular way. Hence, that a patient takes no advantage of means that are ready at his hand is no proof of his safety, for he may only be waiting to avail himself of some other means upon which he has determined. He may allow razors and pistols to lie in his room unused, and then drown himself at the first opportunity.

SUDDEN DESIRE FOR SELF-DESTRUCTION.

Again, the desire to destroy oneself may be created suddenly by the sight of means by which it may be gratified, just as sane men looking down from a steeple or a bridge feel impelled to throw themselves into the street or the stream below.

We know concerning this patient that there have before been insane members of his family, and that he was himself of intemperate habits, two items of information which we are apt to get regarding most of the patients admitted, at least to this asylum.

As to his present condition, you see that he is restless and apprehensive, and he inquires if he is about to be killed. This is a constant source of dread to him, notwithstanding the fact that he attempted his own life. Everything that happens seems to him to threaten the fate he fears. If a wagon stops at the door, it has come for his body; if a dark cloud crosses the sky, it is an unmistakable omen. This selfishness, if we may call it so, is characteristic of the insane of this class. They take everything that they see, or hear, or read, to themselves. Especially is the latter

the case with the Bible, and the denunciatory passages above all. Under their dictation the right hand is cut off, or the right eye plucked out; and so the danger of self-mutilation is added to that of self-destruction.

Finally this man adds his testimony to that of the other upon the point of the influence of secret societies for his sufferings, for he tells you that the "Grand Order of Accepted Bakers," whatever that august body may be, is punishing him for revealing its pass-word.

MELANCHOLIA OF THE RELIGIOUS TYPE.

CASE III.—The succeeding patient is, as you see, quite grief-stricken, his eyes are full of tears, and he moans very grievously. His reason, as he gives it, is that "everything is going wrong," a formula by which the same question, similarly addressed, is often answered. He tells you that he has lived a bad life, that wicked thoughts keep coming into his mind in spite of himself, that he has committed the unpardonable sin, and that there is no hope for him in this world or the next. He too has the scar upon his throat of a self-inflicted wound, and he blames his wicked and involuntary thoughts for that. His troubles are chiefly about religious matters and the loss of his soul, and he has at times persistently refused food, and necessitated his being fed with the stomach-pump. In his case his only assigned reason for not eating is that "it is no use, no use;" but this refusal of food is common among the insane in whom melancholia is the form assumed, and for a variety of causes. Sometimes it is due to the suicidal intent, sometimes to hallucinations of sight or smell, which lead the patient to believe that blood or excrement has been substituted for his food, or poison added to it. At other times the dwelling of the patient's mind upon scriptural subjects, of which I have spoken, and the desire to imitate our Saviour in the fasting in the wilderness, are accountable for the abstinence. So it is always necessary in the care of cases of melancholia to assure yourself that they eat regularly and sufficiently, or to take measures for their artificial feeding, if they do not.

BODILY SUFFERINGS IMPOSED BY ENEMIES.

CASE IV.—The next patient is of a considerably higher degree of intelligence and education than most of those whom I can present to you. His occupation has been that of a teacher, and he was at one time well known in the city. His insanity was evidently gradually developing long before it compelled him to abandon his work. He has gathered from listening to the other patients the object of his examination, and he parries questions very cleverly, and keeps his delusions skilfully in the background. It is not until reminded of statements that he has made upon former occasions, and told that if he does not reiterate them now, it must be because he has found out that they were incorrect, that he allows himself to be drawn out. Then his delusions come thick and fast, and are upon every conceivable subject, acknowledging only the rule of which I have before spoken—that the person himself is always the active agent in them.

He is the scapegoat for all manner of sins, and has incurred the active enmity of scores of distinguished individuals, and especially of scientific societies. From his early training he naturally seeks to account to himself for this condition of affairs, and he finds the motive in jealousy of his attainments and intellect. So you see mixed with the evidences of fear and despondency in his appearance and speech no

small share of self-satisfaction and pomposity. He tells you that Charles Dickens wrote *Bleak House* to injure him, because he envied his greater literary power; and he points out, very ingeniously, passages which he claims support his view; and he accounts for his detention here by ascribing it to the jealousy of the Central Park Commission of his superior qualifications as a landscape gardener.

But his chief sufferings have been bodily ones, imposed by his various enemies. He has run the gamut of diseases, and has ills enough now to kill a dozen ordinary men. He refuses to shake hands with me or with you, because several diseases have been conveyed to him in that way. That was how he caught pneumonia, while cancer was communicated to him in soap, and his hydrophobia came from the mixture by his enemies of the saliva of a mad dog in his butter. But perhaps their most nefarious act was the secret hiding of spermatozoa in his rice-pudding, whereby he became impregnated and carried a child in his stomach until the seventh month, when these same enemies gave him an abortant in his tea, and he miscarried at stool.

HYPOCHONDRIACAL ELEMENT.

You see what a strong hypochondriacal element runs through this case. It is to be looked for in all such cases. Indeed, the melancholia is almost of necessity a hypochondria. The converse is not necessarily true also, though the tendency of hypochondriasis is to end in melancholia. But as long as the transition has not been made the former may be distinguished by his utter hopelessness of cure of his supposed ailments, while the hypochondriac, though he may not acknowledge his hopefulness, shows it plainly enough by the persistency with which he seeks new remedies and new doctors.

PECULIAR DELUSIONS.

Delusions of the class which in this patient take the form of belief that he has had a child in his stomach, are not very uncommon ones. You will find several patients who will tell you that living animals inhabit different organs in their bodies. In one case it is a weasel in the abdomen, in another a rat in the skull, and in a third a doctor who moves from one cavity to another and makes himself peculiarly unpleasant in all. In such cases a feeling of discomfort or pain gives rise to the delusion, and after death the discovery of tumor of the brain or cancer of the intestines accounts for the gnawing of the rat or the weasel.

Not only do the patients at times imagine that animals of one or another kind inhabit the cavities of their bodies, but occasionally they imagine that they are themselves transformed into animals, and they forthwith adopt the habits and carriage of the particular animal into which they believe themselves to have been changed. Other beliefs as to changes in their bodies, in their constituents or component parts, are also found. One patient whom I present to you imagines, and will tell you, that his body is on fire, is gradually being consumed, and that portions of it are already gone. This is being done in order to assist in lighting the world, and at night he will point to the moon and gravely tell you that it is his head, or to the street-lamps and assure you that each gas jet is one of his finger-tips, and he will raise his hand to show you that his fingers are missing, though, of course, such is not the case. Another, also present, imagines that he is dead, and that his body is unpleasant to his companions by reason of

putrefaction. Others, again, think that they have died, or have been killed, but that they are now restored to life; and one thinks that this has happened to him three several times, and will describe to you most minutely the exact circumstances of each murder.

HOMICIDAL MELANCHOLIA.

CASE V.—Here is a patient who committed a homicide a short time since, and who has just been sent here by the court for observation. Of the circumstances of the crime I am not informed as yet, and do not therefore know whether the insanity preceded and led to it, or whether it is the result of remorse for the crime. At any rate, there can be no question that he is insane now, and with the most painful characteristics of melancholia. The recollection of his crime seems to torment him constantly, and he is in perpetual fear that his life, too, is about to be taken. He distrusts his fellow-patients and all who come near him, avoids them, or faces them with his back to the wall, and appears to be at all times anticipating a sudden attack. He has refused food, too, though he does not tell us for what particular reason, and it has been necessary to feed him artificially. He shows the usual loss of natural affection and the usual suspicion of near relatives, refusing to see his wife when she visits him, denying that she is his wife, and accusing her of treachery and misconduct toward him. In every way he suffers as much probably as any of the patients before you. It will not, however, be for long, likely, as he is far advanced in phthisis. This is a common sequel or accompaniment of melancholia, and it is the most usual cause of death in such cases. There are two noticeable peculiarities about it when thus associated: first, that it presents almost no rational or physical signs of its presence, and that its existence is often not determined, nor even suspected, until after death; and, second, that there is a marked alternation in the severity of the mental and the physical disturbances, the mind being comparatively clear and rational when the pulmonary disease is at its worst, and becoming clouded and unsettled again as the bodily powers may temporarily improve.

This man is also a murderer; but in his case there was no suspicion of insanity at the time of the commission of the crime, and he was sentenced to state prison for life, becoming insane only after some years of confinement there. His thoughts, like those of the other man, run, as you see, upon the homicide; but he is more aggressive and noisy, clamoring to be let out, and saying at times that people are trying to murder him, and at others that they forced him to commit his crime in spite of himself.

(The wards of the asylum devoted to the reception of patients suffering from melancholia were then visited, and the peculiarities of different cases exhibited and explained by the superintendent and the physicians of the staff. The same general characteristics as observed in the selected cases shown in the lecture-room were here found, with an infinite variety of detail in individuals. Many were evidently beset with hallucinations of hearing, which caused them great distress. The deprecatory answers returned to these imaginary voices showed that threats and denunciations were the staple of their utterances. Many patients spoke of their sufferings, especially at night from electrical influences operating in their rooms; and one affirmed that his enemies had a telephone under his bed, by which they annoyed him much by shouting at him from the city. Dr. Macdonald stated that this had come to be quite a com-

mon delusion in patients becoming insane since the invention of the instrument.

One patient complained that his lungs had been cut out by means of electricity, that people were able to abstract his thoughts from him by means of suction, and then use them to injure him. He had active hallucinations of sight and hearing, and earnestly appealed to the visitors to aid in his escape.

Another, a former practitioner of medicine in the city, but who has now been in the asylum for many years, spoke of himself as the "Emperor of the World," but had his eye covered with a patch of newspaper, and explained that it was necessary in order to prevent his enemies from dropping poison into it.

Still another believed himself filled with tar and grease, consequent upon drinking rum, and inquired anxiously as to his chances of ridding himself of it. He admitted his insanity and expressed anxiety for its cure, but, as a rule, no such admission could be extracted from other patients, all asserting the absolute truth of their delusions, and the impropriety of their detention.)

Original Communications.

A FATAL CASE OF DISEASE ABOUT BOTH HIP-JOINTS,

IN WHICH THERE WAS AN ABSENCE OF THE USUAL SYMPTOMS OF HIP-JOINT DISEASE—RUPTURE OF THE LIGAMENTUM TERES—DISLOCATION OF THE HEAD OF THE FEMUR ON THE RIGHT SIDE.

By CHARLES T. POORE, M.D.,

SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, AND TO CHARITY HOSPITAL, NEW YORK.

On January 21, 1879, I saw with Dr. Gibney, Mary P—, aged five years, whose history was as follows: On December 14, 1878, she was found to have a coated tongue, and complained of considerable hyperesthesia of both lower limbs. On January 11, 1879, her mother reported that she had been walking lame ever since the last date; that on two occasions she had had severe pain at night; had been irritable in disposition, and losing flesh. Her mother now states that the first symptoms began about six weeks ago. She first noticed a favoring of the *right* side in walking, stiffness in the morning, and that the pain was aggravated by using the limb. The pain, when present, was referred to the inner side of the *right knee*, none elsewhere. No injury or exciting cause known; child always delicate, and surroundings poor. During the two weeks previous to her admission into the hospital there was no marked change in her condition. Motion at both hip-joints was free, smooth, and painless. Temperature normal. The child complained of no pain when quiet; stooping always produced it. She stood in a position somewhat resembling genu valgum. On one examination some pain was complained of about the right hip, but on a subsequent examination it appeared to be perfectly healthy.

On examination, nothing wrong could be detected about either hip-joint; motion free and painless in all directions, except that she complained of some pain in the knee when the *left* thigh was strongly flexed. When the left joint was moved patient

made no complaint, but when the left ilium was pressed inward she cried out from pain. There was no swelling about the right or left hip-joint; no change in the fold of the nates. The *right* hip-joint seemed perfectly healthy. There was pain on pressing the crest of the ilium on the *left* side inward, referred to the *left* knee, or upon attempting to communicate motion to the sacro-iliac joint on that side. There was tenderness, or at least the patient complained, on pressure being made over the sacro-iliac synchondrosis of the left side, and there appeared to be some dulness on percussion over that joint; none on the right. In walking or standing she favored the *left* limb, but there was nothing characteristic in her attitude. The examination seemed to exclude any trouble about the hip-joints.

Patient was admitted into St. Mary's Free Hospital for Children, January 23d, and on careful examination nothing further could be discovered.

February 10th.—Since her admission she has been kept in bed. She has complained of no pain day or night. Motion at the hip-joints is the same as at time of admission. Complains only when the ilia are pushed inward, and then she refers the pain to her left knee. For the past few days she has complained of pain in the left knee when she is moved. She rests, when sitting up, on her left side.

February 22d.—She complained of some pain on motion in the left thigh, which was a little flexed.

February 24th.—Examined with Dr. Gibney. The adductors of left limb were somewhat contracted, as well as the psoas and iliacus. What motion there was at the left hip-joint was smooth and free; that in the *right* appeared normal. There was pain and tenderness over the left sacro-iliac synchondrosis.

March 10th.—Complains of pain at night. Temperature normal.

April 3d.—For a week or so patient has complained of pain in the *right* knee, and the thigh of that side has become flexed. Both thighs were strongly adducted. Suffers much pain when moved. Temperature has been elevated at night, reaching 102°, but normal, or nearly so, in the morning. Patient etherized, and with Dr. Gibney made a careful examination. The contraction of the adductors was easily overcome without the use of any force; in doing this a slight relaxation was felt in the *right* thigh, as though a weak adhesion had given way, but nothing was thought of it. Both limbs were fully extended with but slight tilting of the pelvis. There was no roughness felt in either joint; no swelling about the hip-joints. On examination per rectum no abscess could be discovered; in fact, nothing to account for the pain. After completing the examination it was noticed that the *right* limb was shorter than the left, and on applying slight traction the head of the bone was felt to slip into the acetabulum. No fracture, no crepitus could be detected. It was found that the head of the bone could be easily thrown out of the acetabulum upward and backward. As but slight force had been used, we were at a loss to account for this condition, unless the ligamentum teres had given way and that there was disease of the hip-joint.

Ordered extension to right limb.

April 8th.—Urine was found to be dark, smoky, and albuminous, and on microscopic examination granular casts were found.

April 16th.—There has been nothing special to note, except that patient has gradually failed, and today died comatose.

P.M., twenty hours after death. Dr. Gibney present. On inspection nothing abnormal could be seen;

contour of parts about the hip-joints perfectly symmetrical. An incision was made over the *right* joint and the tissue separated from about the capsule. Everything seemed healthy, but on opening the joint it was found to contain thick pus; the ligamentum teres ruptured and softened, allowing the head of the bone to be dislocated upward and backward. The soft parts being separated, the femur was divided just below the trochanter minor. It was discovered that the floor of the acetabulum was diseased in a space about the size of a five-cent nickel piece around the point of the insertion of the ligamentum teres, and partly necrotic. The cartilage on the head of the femur was of a yellowish color, and at the point of insertion of the ligamentum teres showed more evidence of disease. The capsule on its inner surface was thickened and velvety.

Left hip.—The joint was opened in the same manner as the right. There was no pus in the joint-cavity; ligamentum teres perfectly healthy. The cartilage on the head of the femur was white, glistening, and apparently healthy; the acetabulum showed no evidence of disease. The bone was divided just below the trochanter minor; there was found a carious spot about the size of a split pea, but of irregular shape on the upper surface of the head, at a point just below the line of the epiphyseal cartilage; the articular cartilage at the point was destroyed over a small extent; sacro-iliac synchondrosis perfectly healthy.

Abdominal cavity.—Only its lower portion examined. On laying it open, what appeared to be a partially distended bladder came into view, and on pressing upon it thick and offensive pus came from the vagina. On further dissection there was found to be an abscess behind the bladder and between it and the vagina, with a small opening into the latter. It was found that there was a perforation of the right acetabulum; the symphysis pubis was healthy.

On making a longitudinal section through the head and neck of each of the portions of the femur removed, the following was found:

Right.—The bone seemed perfectly healthy.

Left.—There was a point, mentioned above as carious, where there had been a circumscribed osteitis, or rather, osteomyelitis, extending inward and upward from the carious point to a point just up to the epiphyseal cartilage. There were other similar but smaller points of the same inflammatory process scattered throughout the head. The shaft appeared perfectly healthy.

Remarks.—There was evidently an error in diagnosis in this case, yet I do not see how it could have been obviated. There were certainly none of the symptoms usually met in hip-joint disease, except pain in the knee, until February 22d. Pain in the knee is a not unusual symptom in sacro-iliac disease, and the pain caused by forced flexion was attributed to motion communicated to the supposed point of disease, namely, the joint between the sacrum and ilium. I am unable to account for the pain on pressure over the sacro-iliac joint, or the acute pain complained of when the crest of the ilium was pushed inward, as care was always taken not to apply pressure near the hip-joint. I am positive that there was no tilting of the pelvis, nor any limitation of the motion in the hip-joint, until after February 10th. The occurrence of suppurative coxalgia in the right joint cannot be explained on any traumatic theory, nor do I think the disease in the head of the left femur, central osteitis, is susceptible of explanation except on constitution grounds. Coxalgia would probably have

been diagnosed by one who had not watched the case from the beginning; but until the examination, Feb. 22d, I did not think that the joint was affected, and in this opinion Dr. Gibney agreed.

The theory on which the diagnosis of sacro-iliac disease was based was free and painless motion at the hip-joint; pain on pressure over the left sacro-iliac synchondrosis; pain on pressing the left ilium inward. The pain at the knee was explained on the theory that there was an intrapelvic abscess pressing on the anterior crural nerve, and when the right thigh became flexed it was at first considered as a confirmation of the opinion formed of the nature of the disease.

The capsule of the right hip-joint was not distended, but simply contained pus. The partial dislocation of the head of the femur was due to rupture of the ligamentum teres.

It will be noted that in the left femur there was a central osteitis which had involved the external shell of the bone of the head at one point only; that the cartilage was perfectly healthy except over that point, and that the joint was not involved in disease; while in the right joint there was marked disease at the point of insertion of the ligamentum teres into the floor of the acetabulum; that from the condition of the bone at this point it is reasonable to draw the inference that the disease began at this point, and that the joint was involved secondarily, and that it did not originate in the ligamentum teres, and that disease of the pelvis had been of considerable duration.

Looking at the case again, it will be noticed that the disease seemed to be more advanced in the right joint, yet the symptoms of trouble here were much later in showing themselves than on the left side, where the joint itself was not involved in the disease.

A true dislocation of the head of the femur in hip-joint disease we believe to be very rare, and when it does occur the above case explains its cause, at least in those cases in which it happens early in the disease.

I do not think that this case is an example of disease beginning in the ligamentum teres, because the appearance of the floor of the acetabulum denoted a trouble of some duration, while the ligamentum teres was only inflamed, softened, and thrown off, as it were, on account of its attachment to the floor being destroyed by disease. The left side is an example of disease beginning in the head of the bone—central osteitis; and had the patient lived, the joint itself would in all probability have been in time involved secondarily, while that in the right side was a case beginning in the acetabulum, which had gone on until it had involved the joint.

PRIMARY CANCER OF BOTH OVARIES.

SECONDARY CANCER OF MESENTERIC AND BRONCHIAL GLANDS AND RIGHT LUNG.

By C. W. M. BROWN, M.D.,

ELMIRA, N. Y.

THE following case, occurring in the practice of Dr. H. S. Chubbuck, of this city, seems of sufficient interest to place on record:

H. S.—, colored, aged thirty-five; married; was born in Canada. Her mother died when she was a child, of unknown disease; otherwise family history is good. Has never been sick before present trouble. Is usually stout and fat. Catamenia appeared at eleven; always regular; flow scanty, with little pain. Married at twenty-one; has had six children—one

still-born, five years ago. Labors all easy, except fourth, when child was very large. Last child four years ago. Labor easy, and she made a good recovery. She has been well since, until May, 1878, when she noticed abdomen to be enlarging, and had abnormal craving, and repugnance to certain kinds of food. Her abdomen continued to enlarge, and she "felt movements." In September, 1878, she came to Dr. Chubbuck, thinking she was pregnant. Her abdomen was considerably enlarged, but no physical examination was made.

From this time until the following February she consulted several other physicians, and persistently made efforts to produce abortion upon herself by means of medicine and instruments. But, in spite of all her efforts, the abdomen continued to enlarge steadily. Catamenia continued regular, flow becoming less each time, and finally ceasing in February, 1879. Appetite remained fair; bowels were constipated, to relieve which she had recourse to the usual domestic remedies.

When next seen by Dr. Chubbuck, in February, 1879, her abdomen was very large—so much distended that she could walk with difficulty, compelling her to keep a recumbent position most of the time. There was some œdema of the feet and legs.

Her condition was practically unchanged during the next month.

March 11, 1879, she was seen by Drs. Chubbuck, T. H. and C. L. Squires, and Brown, in consultation, when the following notes were taken:

Patient of small stature; much emaciated. Countenance anxious. Abdomen greatly distended, ovoid in form; somewhat more prominent in left iliac region. Feet and legs swollen, and pit upon pressure. Skin of abdomen also pits upon pressure.

Upon palpation, five centimetres to the right, and a little above the umbilicus, is the most prominent part of a tumor, which seems to float in fluid. Shape irregular; can be moved in any direction, but could not be grasped because of large amount of fluid in abdominal cavity.

The bulk of the tumor was on the right of the median line. Wave of fluctuation felt in all directions. Circumference of abdomen at umbilicus 106 centimetres. Dulness on percussion all over abdomen, except a small space in left hypochondriac region, which was tympanitic. Pressure or percussion over abdomen caused no pain. Auscultation revealed a friction rub over prominent part of tumor. Examination per vaginam showed cervix uteri crowded under pubes; os patulous; anterior cul-de-sac nearly obliterated by hard mass crowding upon it. Posteriorly could be felt a lobulated mass separating vagina from rectum, which seemed to yield upon firm pressure with a crushing sound. No movement could be communicated to abdominal growth from vagina. Small English catheter was passed 6.3 centimetres upward and forward within uterus. Examination by rectum showed a similar hard lobulated mass encroaching upon calibre of rectum. An examination of urine showed it to have a specific gravity of 1015, an acid reaction, and to contain no albumen, casts, or sediment.

The next day the abdomen was aspirated, and a little more than eight litres of clear straw-colored fluid drawn.

Nothing new was discovered after withdrawal of fluid, except that the mass was large, and extended to both sides of abdomen, and was apparently separated into two lobes with a deep sulcus between them. The fluid presented the ordinary chemical and microscopic characteristics of ascitic fluid.

March 15th, she complained much of difficulty of breathing, which compelled her to sit up to breathe. Given .06 of quinia sulphate in whiskey every four hours. Right side of chest in front forward flat upon percussion throughout. Back not examined. Next day a more thorough examination showed flatness on percussion all over right side of chest. Auscultation gave bronchial respiration all over front, becoming faint and distant at base. Respiration faint in upper half of back, and absent below. Movement causes dyspnoea. Pulse, 120; small and weak. Respiration 25, when quiet.

After consultation, thoracentesis was performed and 1.48 litres of clear fluid drawn, and considerable cough with free expectoration of frothy liquid followed. After this she gained somewhat in strength, although abdomen steadily filled again, and the right side was wholly flat upon percussion by the 29th. From this time all symptoms became aggravated; appetite and strength failed; expression more anxious. Abdomen steadily grew in size, and by April 9th was as full as before. She was again aspirated, and 5.5 litres of straw-colored fluid containing flocculi of fibrin.

After performing the test described by Thomas, filtering and passing a stream of carbonic acid gas through the fluid, a precipitate of paralbumen fell. No metalbumen was obtained. Paralbumen is said to be contained only in ovarian fluid, and not in ascitic fluid.

The patient's condition was improved for a few days. But strength soon began to fail; abdomen rapidly filled up, and she sank and died of exhaustion on the 14th.

Autopsy was performed in afternoon of the same day by Drs. C. L. Squire and Brown in presence of Drs. Chubbuck and T. H. Squire.

Body much emaciated; no rigor mortis; abdomen prominent. Upon opening abdominal cavity, intestines were found distended with gas. Peritoneal cavity estimated to contain 1.9 litres of fluid.

Two masses appeared; the larger, on the right side of the abdomen, was floating upon the intestines, to which it was adherent over small extent. These masses were the ovaries. The left was firmly wedged down in the true pelvis, pushing the uterus upward and to the right. It was the mass felt per vaginam. They were irregularly rounded, lobulated, yellowish in appearance, and solid in consistency. They together weighed four kilogrammes; the larger being about three times as heavy as the smaller. Upon section, the surface was yellowish or yellowish white, with numerous small cysts containing clear straw-colored fluid. The cysts were often traversed by small trabeculae. A few spots in both, and especially in the larger, were much softer, and contents were found to be semi-liquid. One spot upon surface of larger mass was umbilicated, and such soft conditions were found underneath it upon section.

Uterus somewhat enlarged, and pressed well forward against pubes.

Kidneys somewhat larger than normal, congested; otherwise healthy. Spleen normal. Liver normal in size, but showed some fatty degeneration. Several of the lumbar glands were enlarged. Upon turning back sternum, a growth was found upon cartilage of fourth rib of right side, with hard cartilaginous feel, and yellowish appearance on section. Intercoastal spaces of right side bulged out; diaphragm pressed downward on that side. Right pleural cavity estimated to contain 3.8 litres of clear serum, which coagulated upon cooling to a jelly-like mass. Right

lung pressed into upper and back part of pleural cavity. The upper and part of the middle lobe crepitated. The remainder solid, yellowish. Parts of it are very hard, cutting like cartilage; one spot in centre seemed to be breaking down—was soft and friable. Bronchial glands enlarged from size of pea to that of English walnut. Left lung and heart normal. Head not opened.

Microscopical examination of ovaries showed them to be composed of connective tissue infiltrated with small nucleated cells, which were in some parts arranged in collections or nests, the so-called "cancer nests." They are therefore cancerous.

The question of diagnosis in this case was one of great interest. The case had been seen by several medical gentlemen of this city before she came finally into the hands of Dr. Chubbuck, and had by most of them been called one of uterine fibroid. After the consultation held, opinions were divided, a part calling it multiple uterine fibroid, regarding the floating mass as a fibroid attached to the uterus by a pedicle, and the part felt per vaginam, to which motions could be communicated, as a separate subperitoneal fibroid. The others called it cancer of ovary, with possibly a fibroid of the uterus. The rapid growth of the tumor while under observation, with the increasing ascites and progressive failure of general condition, pointed strongly toward a cancerous disease, but the question was only settled by post-mortem examination.

The diagnosis of cancer of the ovary is always difficult. Thomas mentions two cases which he diagnosed as cancer of the ovary, which proved to be benign growths.

All recent writers agree that primary cancer of the ovaries is very rare.

Wells only found three cases in his first four hundred ovariectomies, and Peaslee, writing in 1874, thinks that with our present knowledge, these were not cases of cancer. Charles Clay only saw six undoubted cases in five thousand diagnosed cases of female disease. Peaslee only saw two cases in two hundred ovariectomies and autopsies. He agrees with Fehr, that it is the least common of all diseases of the ovary. It usually attacks both ovaries, as in the present case. It does not occur with especial frequency in elderly women, according to Schroeder, but evinces a special predilection for younger subjects, and may even occur before puberty.

Cancer of the ovary occurs in two different forms, according to Schroeder: the first as a diffuse infiltration of the stroma, so that the entire ovary is transformed into a cancerous mass covered with peritoneum and retaining very nearly the form of the ovary; or more rarely it happens that one or more cancerous nodules are found in the otherwise healthy tissue, which grow very large, and thus transform the whole ovary into a nodular tumor. The present case evidently belongs to the more common form. Ovarian cancers are usually small. Peaslee says they rarely become larger than an orange. Yet he quotes Lebert as reporting one which weighed eleven pounds, and J. L. Brown one which weighed nineteen pounds.

The disease always severely irritates the peritoneum, and thus always causes ascites, and sometimes limited acute peritonitis. The ascites seems to have appeared rather late in this case. But that there was an inflamed state of the peritoneum was shown not only by the ascites, but by the adhesions to the intestine and lymph in fluid at the second tapping.

A CASE OF NEARLY FATAL HEMORRHAGE FOLLOWING THE SIMPLE OPERATION OF CANTHOPLASTY.

By D. B. SIMMONS, M.D.,

YOKOHAMA, JAPAN.

K—, a female servant, in the employ of one of the foreign residents, presented herself at the outdoor service of the hospital, with ulcerative keratitis.

As an auxiliary means of treatment I performed the ordinarily trivial operation of canthoplasty. Though there was pretty free bleeding at the time, pressure and cold applications caused it to cease entirely in the course of twenty-five or thirty minutes. The patient then started on her way home.

Before she had gone far, however, the bleeding came on afresh. As she was of the impression that free bleeding would have a beneficial effect on the eye, she took no means to stanch it till she felt herself becoming faint, when she called for help, and her master took the matter in hand.

The operation was performed about 10 A. M., and I was called to see her at 8 o'clock the same evening. I found her condition truly alarming, though the bleeding had ceased a short time before I arrived, and did not return. From the appearance of her clothes, the bedding, including the mattress, and numerous towels which were laying about saturated with blood, there was an easy explanation for her all but moribund state. The pulse at the wrist was imperceptible; lips and face without color; hands and feet cold; and the whole body bathed in a cold perspiration. As this state had lasted for over an hour, no means but transfusion, it appeared at the moment, could save her.

Not having the appliances at hand for performing the operation, I made use of the ordinary means for resuscitation, such as hot bottles, brandy by the mouth, rectum, and hypodermically, to which was added later ether. At the end of an hour's hard work the pulse at the wrist returned, though only for a few moments, following a large potion of stimulants.

Toward morning, however, I left her out of danger, and her recovery was complete. I can only explain this extraordinary loss of blood on the theory that I had divided an anomalously disposed artery, or a hemorrhagic diathesis, though I suspected nothing of the kind immediately before or after the operation.

October 10, 1879.

THE PLASTER-OF-PARIS CORSET.

By S. HEMINGWAY, M.D.,

EXAMINING PHYSICIAN TO DEPARTMENT OF CHARITIES AND CORRECTIONS, BELLEVUE HOSPITAL, N. Y.

Among several objections to the use of the plaster-of-Paris jacket are: the difficulty of constructing a jacket that can be applied and removed at will; the fact that if a jacket is once taken off, it is useless, unless it is sent to an instrument-maker to be riveted, etc., at quite an outlay; that the jacket will invariably break in front if cut; the inability to preserve cleanliness without destroying the jacket, and the difficulty, at times, of securing a perfect fit. These objectionable reasons against this valuable auxiliary to the treatment of spinal curvatures, etc., are, I think, fully overcome by the use of the plaster corset. To apply the corset, the patient is suspended in the usual manner. A strip of muslin, sufficiently wide to neat-

ly cover the thorax and abdomen, and long enough to extend a little over one-half the length of the jacket above and below, is neatly pinned over the seamless shirt used in applying the jacket. The muslin is subsequently to be turned over the jacket, thus lining both surfaces. After a layer of plaster bandage and plaster have been applied, the strips *A* and *B* are

laid perpendicularly upon the plaster, on a line about two inches within the inner edge of the axilla, in front. The jacket is now finished in the usual manner; but before completing it, the muslin above and below is to be firmly and neatly drawn over the jacket, overlapping at the centre, and is held in place by a turn or two of the bandage, thus lining the jacket. The jacket is now divided in the median line in front; and, after making apertures in the muslin for the hooks, the canvas strips (*C*) are hooked on, and the corset is laced up with the ordinary corset-lace.

To prevent crumbling of the cut edges of the plaster, when they are dry. I have found the excellent rubber plaster of Scabury & Johnson will as effectively protect the edges as if riveted on, when the plaster is heated and applied. The strips of iron are made of hoop-iron, and the hooks are the ordinary five-eighth brass hooks. Ordinary canvas or leather strips will answer for lacing the corset. The iron strips should have as many hooks as will allow a space of two and a half inches (the width of an ordinary bandage), between each; and they should also have a perforated zinc or tin strip to retain them in position, and to give them support. The proper length of the strips can be estimated with accuracy by measuring the distance from the axilla to the crest of the ilium, care being taken that the upper and lower hooks shall be respectively at the extreme top and bottom of the strip. The cost of the necessary materials for the corset is about twenty-five cents, and can be made by an ordinary mechanic. Where there is a necessity of removing the corset frequently I have used a double \square , made of perforated tin strips, placed in the back of the corset. Through the courtesy and with the assistance of Dr. V. Mott, I have applied the corset to several of the patients in his orthopedic class in the out-door department of Bellevue Hospital.

One of these patients, a girl, *æt.* 10 years, had a sharp, angular curvature in the lower dorsal region. She had had the jacket applied previously, but ulceration on the apex of the curvature was not discovered until pus was found staining the shirt, below the jacket. Although in great pain without the

jacket, she could not wear it, owing to this sloughing of the integument over the curvature.

I have applied the corset to her, and by occasionally removing it, no trouble has as yet occurred, and she remains free from pain.

What I claim for the plaster corset is this: It costs almost nothing. It can be immediately applied, without the necessity of taking a cast. The increase of weight in the corset is almost *nil*. If too tight it can be loosened, and *vice versa*. It can be removed and applied at pleasure. It is lined within and without. Cleanliness is not interfered with. The iron strips in front prevent its breaking there, which is the first point to give in the jacket; and, the strips behind, when used, give it additional strength and durability.

145 EAST THIRTY-NINTH STREET, N. Y.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

ANEURISM AT THE JUNCTION OF THE TRANSVERSE WITH THE DESCENDING PORTION OF THE ARCH OF THE AORTA.

The following case exhibited certain points of interest relating to symptomatology, etiology, and treatment of aneurisms: A male patient, *æt.* 41—a fireman—a habitual drinker, had syphilis sixteen years ago (primary sore and secondary manifestations); in August, 1879, while engaged daily in lifting heavy weights, he began to feel shooting pains in the left side and arm, especially towards night, and finally experienced a sensation as though something suddenly gave way. Following this, he suffered considerably from shortness of breath, had a slight cough, and lost flesh rapidly. The symptoms during the month of September, with the exception of the losing of flesh, remained about the same, and on the 8th of October he felt a severe pain in the left side, which was accompanied by great dyspnoea. Speech was normal; there was no vomiting, and the urine was normal. He was admitted to the hospital October 12th. There was nothing specially noticeable relating to general symptoms. On physical examination of his chest it was found that there was little or no expansion of the left side; flatness on percussion in front and behind; absence of respiratory sounds at the upper part of the left side, feeble below, and bronchial breathing behind. Voice sounds were heard over the entire left side of the chest. The bronchial respiration might be explained in two ways: 1. It might arise from the lung by a tumor, or it might be that a tumor was so close to the chest-walls as to transmit the true tracheal and bronchial sounds.

There were no cardiac murmurs. A prominent pulsating swelling existed just below the left clavicle. It was dull on percussion, tender on touch, did not give thrill or fremitus, and no murmur could be heard over it.

The apex of the heart beat against the chest-wall so distinctly that it seemed almost possible to take the organ in the hand. It apparently moved from right to left with each pulsation of the heart, and was in the sixth intercostal space below and to the left of the nipple. From the strength of the cardiac impulses it was thought that the heart was hypertro-

phied; but probably the displacement of the apex was partially due to the pressure of the tumor downward. There was no aneurismal murmur, yet it was said that that fact did not militate against aneurism; for, although in the majority of cases of aneurism a murmur exists, there are cases in which it cannot be heard. On the other hand, no matter how loud and rough a murmur may be present, it alone is not evidence of aneurism.

The radial pulse upon the left side was weaker than upon the right. There was no change in the pupil on the left side.

There was no transmission of the normal cardiac sounds to the tumor—a symptom strongly in favor of aneurism when present. Before admission to the hospital, the patient had been treated for pleurisy.

Rest, nutritious diet, and the internal use of iodide of potassium, were the essential factors of treatment.

ANEURISM—ABSENCE OF PHYSICAL SIGNS—RUPTURE INTO A PRIMARY BRONCHUS.

In connection with the above, a case was mentioned in which the patient, a man in middle period of life, was supposed to be suffering from asthma, simply because he had recurrent attacks of dyspnoea. A careful examination of the chest gave entirely negative results, and the absence of dry râles, so uniformly present in the chest between the paroxysms of asthma, excited the suspicion that the man had an aneurism. A croup-like cough was heard, and the suspicion was increased, but no evidence of aneurism could be found. Some weeks afterward the patient had small hæmoptysis. Careful physical examination was again made, but no marked evidence of aneurism was found. He passed into the hands of a homœopathic practitioner, who diagnosticated dyspepsia, and said the patient must have exercise. Autopsy revealed a small aneurism projecting in such a manner as not to give rise to marked physical signs; but it had ruptured into a primary bronchus, and caused almost instant death. The case was interesting because it illustrated the significance of spasm of the glottis.

CIRCUMSCRIBED PLEURISY—UNSUCCESSFUL ASPIRATION—PERFORATION OF LUNG—GOOD PROSPECT OF RECOVERY.

A male patient, æt. 30, came into the hospital, and on physical examination gave evidence of bronchitis, which was followed by the physical signs of lung consolidation, and subsequently by evidence of liquid in a circumscribed space in the right side, just below the scapula. A hypodermic needle was introduced twice and fetid pus was drawn out, and yet pus was not obtained by means of an aspirator. Aspiration was not persevered in, and after a short time the man began to spit up fetid pus freely. The expectoration of this material continued for a few days, then began to subside, and at the date of our visit its fetid character had disappeared, and the patient's general condition was improving quite rapidly. When dulness on percussion occurred, it was thought to be a case of lobular pneumonia. From the fetid character of the expectoration, it was inferred that a small patch of gangrene occurred in the lung and gave rise to circumscribed empyema.

ACUTE EMPYEMA—ASPIRATION—PERFORATION OF THE LUNG, WITH EXPECTORATION OF FETID PUS—CASE PROGRESSING FAVORABLY.

In connection with the above, mention was made of a case in which the physical signs of liquid in the pleural cavity were developed in a middle-aged man

who had been previously in the enjoyment of what he supposed was perfect health. An aspirator-needle was introduced, and between fifty and sixty ounces of fetid pus were withdrawn. He was aspirated the second time; subsequently perforation of the lung occurred, and the patient expectorated an enormous quantity of fetid pus. Expectoration of pus continued for some time; but his appetite returned, he regained strength, and finally the expectoration ceased. About four or six weeks afterward he again expectorated a considerable quantity of the same kind of pus, but his general condition was not affected unfavorably, and he was steadily improving.

CHRONIC DIARRHŒA—CHRONIC CATARRHAL INFLAMMATION OF THE LARGE INTESTINE—INDICATIONS IN TREATMENT.

A male patient, æt. 50, a moderate drinker and a tailor by occupation, had, during the last seven years, been subject to diarrhœa. The discharges had been large, fluid, and had occurred as a rule soon after taking meals; this had been the course, especially during the last week. At the time of admission he was not much emaciated; although at one time previous to his admission his diarrhœa was profuse—as many as twenty-four large watery passages occurring daily—and the passages were excited by anything taken into the stomach, even a drink of water. The fact that the discharges were large excluded the lower portion of the large intestine as the seat of the lesion that gave rise to the diarrhœa; but the fact that the discharges were excited by ingestion of food, led to the conclusion that the lesion was situated in the large rather than in the small intestine; for there is a pretty well-marked sympathy between the colon and the stomach, rather than between the stomach and the small intestine. This is so marked in some cases, that as soon as anything is taken into the stomach, there is a desire to have a passage from the bowels; but it is not, as patients usually suppose, because "the food goes directly through them," but because it acts as an irritant upon the rectum, and at once gives rise to the desire to get rid of whatever there is in it. It was believed that the lesion in this case was simple chronic catarrhal inflammation of the mucous membrane of the upper part of the large intestine, and that it had existed during the past seven years.

If, as was supposed, the lesion was situated in the large intestine, and the irritability of the large intestine was kept up by the presence of food in the stomach, the first indication in treatment was *not* to irritate the stomach, and thereby avoid the exciting cause of the discharges. How could that be accomplished? The simplest plan, it was stated, was to put the patient on a milk diet. In many cases, not in all, the milk does not irritate the stomach. A certain portion of casein will be digested, and the remainder will be digested in the small intestine. Again, as the result of experience, it was known that chronic inflammation of the upper part of the large intestine was frequently best treated by rest, and a diet consisting principally of fat in the form of either cream or cod-liver oil. By placing a patient on a milk diet, both indications were fulfilled. Such had been the treatment in this case, and he at once began to improve. The real difficulty, however, it was said, in treating such cases was to change from the milk to some other diet, when a change became desirable or necessary. An ordinary history is that, while they adhere rigidly to a milk diet, it is cured; but as soon as they return to ordinary food the diarrhœa returns.

That was the effect in this case: improvement on milk diet; return of diarrhoea when ordinary food was substituted for it.

How are they to be permanently cured? If complete control can be had of a patient, this can be accomplished in many cases by introducing the ordinary diet very gradually. First, stop the milk entirely, not continuing it with other articles of food. Then very carefully regulate the quantity and quality of the food which the patient is to take. The first article used to the best advantage is meat—beef or mutton—finely cut and taken in small quantities at a time; and to this, perhaps, a small quantity of toast and tea, or an egg, may be added three times a day. After a few days perhaps rice can be added, and so, adding the most easily digested articles, the patient may be gradually changed from one diet to another. If the diarrhoea returns, the patient should at once be put back on a milk diet. The gradual transfer to the ordinary diet is sometimes aided by certain drugs. For a patient of this age the mineral acids and preparations containing strychnia were said to be the best that can be employed, taken with the meals. The following was recommended:

R. Tr. nucis vom. gtt. xx. -
Acid. nitro-muriatic. dil. gtt. xx.

Mix; dilute well with water, and take three times a day, with meals.

In this way these cases can be not only temporarily, but permanently cured.

Progress of Medical Science.

CEREBRAL THERMOMETRY.—Doctors Maragliano and Seppili, of Reggio-Emilia, Italy, have undertaken some interesting investigations into the cerebral temperatures of the insane and the sane, in the latter confirming in the main the observations of M. Paul Broca, of Paris, and Dr. L. C. Gray, of Brooklyn. Their essay was read before the medical congress at Pisa, Sept. 28, 1878. The conclusions in regard to the insane are as follows: 1, it is exceptional to find the average temperature of the head higher than normal in simple lipomania and dementia; 2, the highest temperature is found in furious mania, 98.40°; then, in decreasing ratio, in lipomania agitata, 98.25°; in progressive paralysis, 97.93°; dementia agitata, 97.61°; imbecility and idiocy, 97.41°; simple mania, 97.34°; simple lipomania, 97.10°; simple dementia, 96.85°; 3, in all mental diseases the occipital lobes are of lower temperature than the others; the temperature of the frontal lobes, which equals that of the parietal in dementia agitata, in idiocy and imbecility, is higher in mania, in simple lipomania and simple dementia; whereas in progressive paralysis and in lipomania agitata the temperature of the parietal lobes is higher than that of the frontal; 4, in all the principal groups of mental diseases the averages of the two sides of the head are almost equal, with the exception of congenital forms, in which the various regions of the right side show a higher figure than the left; 5, the results of cerebral thermometry, compared with what we know of the pathological anatomy of the diseases under consideration, tend to show that in progressive paralysis, mania and the different periods of exacerbation which often manifest themselves in forms of mental depression and debility, there exists a hyperæmic condition of the brain; 6, the general

temperature of the body of the insane, taken in the axilla and rectum, is higher in lipomania agitata and mania furiosa, and generally goes on decreasing in regular order in progressive paralysis, dementia agitata, simple mania, imbecility and idiocy, dementia tranquilla and simple lipomania. These authors found the cerebral temperature of the sane to be higher than did Broca and Gray, their figures for the individual lobes being on the average 3.54° greater, whilst they found the whole head 3.47° warmer. They explain this disparity by the fact that they did their work in June, July, and August, whilst Broca and Gray performed theirs in the winter and early spring. In fact, the Italian investigators made some observations in December, and found the figures very nearly those of Broca and Gray. Thus, they conclude that the disparity is explained by the difference in the surrounding atmosphere. Prof. Maragliano ascertained that thermometers placed on the skull were accurate indices of the temperature of the contents of the skull. He filled a skull with water at different temperatures, leaving the integument and hair on, and he found that the thermometers placed externally followed faithfully the oscillations of temperature of the water within as denoted by thermometers placed therein. He also found that during sleep induced by chloral there is a constant decrease of temperature. In three cases of cerebral embolism, too, he found the temperature decreased.—*Studi di Termometria cerebrale negli alienati.—Riv. sperimentale di fraenitria e medicina legale.*

THE OPERATIVE TREATMENT OF GENU-VALGUM.—Dr. Thomas F. Chavasse has prepared a very clear review of this subject, and the following are the operations as practised at the present day: 1. Osteoarthrotomy. 2. Osteotomy. 3. Subcutaneous fibrous section. 4. forcible straightening. The first is known as Ogston's method, and is done by flexing the knee as fully as possible, then inserting a long tenotomy knife flatly, two or three inches above the tip of the internal condyle, pushing it downward, forward, and outward, until the point is felt in the inter-condyloid space. The cutting edge of the tenotome is then turned downward, and the soft tissues are divided to the bone as its withdrawal is effected. Adams's saw is now inserted and directed along the canal which has been formed, and the inner condyle is sawn through from above downward for about three-quarters of its thickness. By forcibly straightening the leg, the fracture of the partly detached condyle is completed, and the limb brought into proper position by the loose condyle slipping upon the sawn surface of the shaft. The after-treatment is simple. Schmitz, of St. Petersburg, and Mr. Reeves, have made modifications of this, though both practically amount to the same. The former makes an open wound, and the latter does what he terms a "subcutaneous extra-articular osteotomy." Reeves uses a chisel. It has been proven, however, that the joint is opened either by the chisel, or by fissure when the limb is straightened. Hence Dr. Chavasse very justly considers this an osteoarthrotomy.

Macewen, of Glasgow, and Chiene, of Edinburgh, lay claim to the operation by osteotomy, *i. e.*, the removal of a wedge-shaped piece of bone from the femur above the line of epiphyseal union. Macewen takes a point half an inch above the upper border of the patella, while the leg is in a state of extension, makes an incision just in front of the tendon of the adductor magnus, reaching the femur at one cut, the length of the wound being about three-

quarters of an inch, and then divides the shaft of the bone for the inner two-thirds of its thickness by three chisels, the largest of which is used at its commencement; thus a wedge-shaped opening is produced without removal of osseous material. The remaining outer third of the shaft of the femur either snaps or bends when the leg is straightened.

Barwell and other operators divide the tibia in addition to the femur, and occasionally the fibula also.

Langenbeck stands first among those advocating spontaneous fibrous section. He divides the external lateral ligament. Billroth divided the external ligament and the tendon of the biceps, while Reeves has divided, in addition to the above, the fascia lata.

The Lyons School, and especially M. Delore, recommend *forcible straightening*. It is carried out by placing the subject on the back, and after administering an anesthetic freely, by main force with the hands and knees of the operator, bringing the leg into the normal position; this, if effectual, is accomplished by a series of cracks. Sometimes the strength of the operator is not sufficient, and Rizzoli's osteoclast is recommended. Macewen and Reeves have failed to produce any effect by this *redressement forcé*. English surgeons regard this as a rough unscientific operation, and one not to be recommended.

Dr. Chavasse gives the arguments *pro* and *con* for the different operations. One Ogston operation has resulted fatally.

The chief objection to osteo-arthrotomy is the involvement of the joint. No operation can be a safe one that involves the articulation. Ogston's, Reeves', and even Chiène's, which professes to be a pure osteotomy, have all been proven to implicate the articulation, and are hence attended with more or less danger.

He sums up by saying that the number of plans that are now advocated is in itself an argument that the correct method is still to be ascertained; and that if the exact pathological causation can be decided upon, there is but little doubt that practical surgery will speedily indicate the precise and proper treatment of the malady in question.—*Birmingham Medical Review*, October, 1879.

A BRIEF RECORD OF TWO THOUSAND TWO HUNDRED CASES OF MIDWIFERY.—The following is a summary of 2,200 consecutive cases of midwifery occurring in the private practice of W. Whalley, M.D., of Bradford, England. There were thirty-nine breech-presentations, of which seventeen infants were still-born. Footling cases occurred seventeen times; ten of these infants were still-born. The arm presented twelve times; five of these infants were still-born. The face presented five times; one infant was still-born. The funis associated with either head or breech-presentation occurred seven times; one infant being still-born. The funis and arm presented in one case, the infant being still-born. The funis and shoulder presented once; the funis, feet, and head once; the funis and foot once; the shoulder once; the foot and head twice; the hand and face once. There were two complete and three partial placental presentations. The placenta was retained or adherent in twenty-seven cases, requiring the introduction of the hand for its removal. Accidental hemorrhage occurred in twelve cases. In three instances the funis was coiled three times around the neck of the child. The long and short forceps were applied in fifty-one instances, in which seven in-

fants were still-born. Craniotomy was resorted to in eleven cases. Podalic version was performed in about twenty-one cases; and the Caesarian section in one case.

There were twenty-eight cases of twins, of which eleven infants were still-born. In thirteen cases the head presented in both children; in seven cases, in the first child the head presented, and in the second the breech; in four cases the head of the first child and the foot of the second; in one case, the arm of the first child and the head of the second; in another, the breech of the first child and the head of the second; in one case, the head of the first child and the hand of the second; and in another, the hand of the first and the head of the second. In half the number of cases, the second child followed the first at intervals varying from twenty minutes to two hours; in the remainder, the intervals varied from two to six hours. In twelve cases the children were both males; in seven, both females; in five, male and female; and in four, the sexes were not registered.

Rupture of the perineum requiring surgical interference happened in six cases. All were successfully treated with the quilled and interrupted sutures. Spontaneous evolution occurred in three premature cases. Five cases were complicated with convulsions. Deformity of the pelvis was met with in seven cases. Premature labor happened spontaneously twenty-eight times, and was artificially induced five times.

In one patient, seven years had elapsed since her last confinement; in another eight; in two, nine; in one, ten; in one, eleven; in one, twelve; in one, fourteen; and in two, fifteen.

Among the primiparae, six patients were aged respectively 32, 34, 36, 37, 39, and 45 years.

Of the total number delivered, seven mothers died.

The abnormalities met with in children were the following: Three possessed supernumerary thumbs; in two of these cases the redundant thumb was amputated, and in the third the ligature applied; all did well. One child had webbed fingers; another, hare-lips with cleft palate; the latter was successfully operated upon at the eighth week. One child was born with talipes calcaneus, and was successfully treated by the aid of a boot without division of tendons. There was one case of spina bifida, the tumor being situated in the lumbar region; and, notwithstanding every care was taken to protect it from injury by a properly arranged apparatus, the child only survived a few months, ultimately dying from convulsions. There were twelve or fourteen cases of *mevi*. Two were cured by vaccination, one with nitric acid; but the ligature was found most successful. One child had malformation of both ears; each pinna or external ear consisted merely of a small thip of loose skin, and there was complete absence of the meatus auditorius externus; the child did not survive many days. In another child there was an absence of a portion of the abdominal parietes in the umbilical region, the deficiency being supplied by a purple-colored membranous structure; the child died before the funis separated. Lastly, there was one acephalous child.

Dr. Whalley has employed the forceps much more frequently of late years than formerly, because patients have learned to appreciate their utility. The long instrument with the pelvic curve was invariably used and found to answer every purpose, whether the head was engaged at the brim of the pelvis, or in the cavity, or at the outlet.—*The British Medical Journal*, September 30, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, November 22, 1879.

CONCERNING THE LAW AGAINST QUACKERY.

In the recent report of the Board of Censors of the Medical Society of the County of New York, there are some matters, bearing upon the prosecution of illegal and unqualified practitioners, which are of general interest.

It may be necessary to premise by saying that this State, in common with many others, has a law against quackery. That it is an imperfect one is no surprise to such as have watched the history of medical legislation, and are acquainted with the difficulties attending it.

There are so many influences at work to defeat the best purposes of the framers of such bills, that it is impossible to do anything more than make a show of reform.

There has never yet been a law for the prevention of quackery which has not been inoperative in its most important features. The present law of 1874 is no exception to this rule, as proven by those who have had the opportunities for testing its provisions. So far has it failed of its desired effect, that, in the language of the report, "it might with more propriety have been styled an act for the promotion and protection of quackery."

When the act to which we refer went into force, the Censors, with a zeal worthy of the cause, proceeded to discharge their legal duties by summoning before them for examination all unqualified practitioners, and those practising without a diploma. Such as appeared for examination were, if qualified, granted "certificates of qualification." But it was found that these certificates were not to be considered licenses to practice unless authorized by the Society through its president.

The very fact, however, that any chartered medical societies in this or any other State are authorized to give such licenses, is in itself liable to such abuse

that the Censors recommend its abolition. The report very suggestively says: "As any five physicians may, under the general statutes of the State, associate themselves for medical purposes, and become an incorporated or chartered society, it will be readily perceived that the opportunities for the abuse of the licensing privilege are at present very great, and in the near future may even become still greater. In the whole of Great Britain there are, we believe, only about twenty licensing bodies, while in this State alone there are probably between one hundred and one hundred and fifty. In this county there are at least twelve bodies that habitually exercise this power. Under these circumstances, the Censors believe that it would be better if this and all of the other medical societies in this State were deprived of the power to issue licenses. It would, at all events, tend to diminish the number of avenues by which unqualified persons acquire by law the right which should alone pertain to those who are properly qualified by education."

In regard to the question of bogus diplomas there have been found many obstacles to encounter. There does not seem to be a doubt, if the holder of such a diploma were prosecuted, the court would decide that such a document had been illegally obtained, and would inflict the requisite penalties. The difficulty would be in obtaining the requisite evidence, and even then but one offender against the law could be reached. Little would in reality be accomplished so long as the "diploma mills" were left undisturbed. In the opinion of the Censors, the only effectual way of destroying the abominable traffic would be by appealing to the courts to annul the charter of the offending institution. Then again, the case being brought, as it necessarily would be, in a civil court, the defendant would naturally resist, and the expenses of the prosecution would be greater than the Society would have a right to expect any single one of its members should bear.

After stating the impediments in the way of enforcing the provisions of the act, the report offers a suggestion as to how illegal practitioners may be prosecuted. It goes on to state that the offence being a misdemeanor, it is the duty of the District Attorney to prosecute on the complaint of any citizen or corporation that can furnish him with evidence sufficient in his judgment to insure conviction. In other words, the complaint may be made by any member, in his own name, or the Society can, by a general resolution, direct the officers, as its representatives, to make the complaint in the corporate name of the Society.

After all, the burden of collecting evidence is upon the profession, and the proviso that such evidence shall be sufficient in the judgment of the District Attorney to insure conviction, is, considering the loop-holes in the present law, no easy matter.

THE VENTILATION OF CHURCHES.

Dr. O'SULLIVAN, in an address on State Medicine, delivered at a recent meeting of the Medico-Legal Society, calls attention to the very important subject of defective ventilation in Catholic churches. He says very truly that in such places of worship, which are crowded many hours in the day, the air is foul in the extreme, and saturated with the germs of disease. No sooner is one audience dismissed than another enters, the only means of changing the atmosphere in the meantime being through the open doors. The latter are generally blocked by an incoming and outgoing crowd, so that, practically speaking, there is no ventilation whatever. Add to the dangers of breathing over and over again this bad atmosphere, the chances of propagating disease by the unrestrained admittance of nurses of the sick and convalescents from contagious disease, we have a state of affairs which deserves the gravest consideration. Dr. O'Sullivan very properly urges the clergy to adopt necessary measures for ventilation between services, and also suggests that nurses during their attendance on the sick should absent themselves from mass.

NEW MEDICAL COLLEGES.

It requires very close watching to keep track of all the new medical colleges that are springing up. We have now to announce a fifth medical college for the State of Indiana. This last educational acquisition is located, to speak more definitely, at Indianapolis, making the second medical college in that city.

Although not so stated in the announcement, the college is, it is said, the offspring of personal ambition, and private quarrels chiefly. The *American Practitioner*, in commenting on this new organization, refers very pertinently to the vastly greater need of medical legislation than of medical education, so called. Some laws are needed to prune out a little of the wretched stuff that is demoralizing the medical profession now—laws that will prevent a few men, actuated by selfish ambitions, from pouring thousands of raw and ill-conditioned young men every year into communities that do not need them, and into a profession that they only help to belittle. There is no need of more medical colleges; there is need that there be fewer young graduates, and that the power of conferring licenses be taken from the existing schools and given to the State. This is the general feeling of the profession. Nevertheless, there can be recorded five new medical colleges—and there may be more—that have been announced in the United States this fall. We must conclude that, if a doctor has a chance to stand up and talk before a few gaping students and get "Professor" attached to his name, he will not care what the voice of the profession is. This state of affairs will last, however, until

medical men do something besides grumbling; until they are roused to take the matter into their own hands and demand laws which will protect themselves in the pursuit of their occupation, and in their desire to acquire, honestly, support and reputation.

RESULTS OF SANITARY EFFORTS IN NEW YORK CITY.

The report of the city health board shows that the most gratifying results have attended the efforts to improve the condition of the city's sick children during the past summer months. The means adopted have been sea-side homes, excursions to country towns, large excursions, and regular medical visits to the tenement-house population. Everything, except the last, has been under the direction of private charitable organizations.

It is shown that, whereas in 1875 the deaths from diarrhoeal diseases, mainly amongst children, were 2,997, and in 1876, 3,060; in 1877, the year in which sanitary measures were more actively enforced, there were only 2,657; in 1878, about 2,057; and in 1879, about 2,081. There has thus been a reduction in this particular death-rate, of nearly a thousand. This means a reduction also of about 25,000 cases of sickness.

The general mortality of the city, however, has not been proportionately diminished; and private charity has done quite as much as public in securing this special result.

Reviews and Notices of Books.

SEEING AND THINKING. By the late WILLIAM KINODON CLIFFORD, F.R.S. London: Macmillan & Co., 1879. 8vo, pp. 156.

This is the eleventh volume of the "Nature Series" of popular scientific works. It consists of four lectures delivered by the author before general audiences. Professor Clifford states that his subject is a sort of "Clapham Junction" of all sciences, and the contents of the book justify the statement. Physics, astronomy, physiology, and psychology are all introduced. We have no space to discuss the book at length; it is, however, an admirable one, and we doubt whether so intricate a subject was ever more simply and clearly exposed. Excellent diagrams and illustrations accompany the text.

A TREATISE ON VOCAL PHYSIOLOGY AND HYGIENE, with especial Reference to the Cultivation and Preservation of the Voice. By GORDON HOLMES, L.R.C.P., Edinburgh. London: J. & A. Churchill, New Burlington Street, 1879. 8vo, pp. 266.

The author of this book states that his aim in writing it has been to furnish singers and speakers with a concise and complete account of the scientific relations of the voice, physical and medical. A remarkably broad field has certainly been gone over in the compass of his three hundred and seventy pages. The author begins with the origin of language, and from this trips lightly through ages prehistoric, classical and mediæval, bringing us in one chapter to

the subject of modern acoustics. This necessarily involves much conciseness, and it may be questioned whether such a historical review is of much value. Under the head of Sound and Voice, the elementary principles of sound are given in a very satisfactory manner. The larynx is considered, as is usual, to be a reed instrument, and its anatomy and physiology are described. A chapter on the physiological principles of vocal culture, and one upon the hygiene of the voice, complete the work. To the physician this book will furnish some interesting physiological points on the subject of the production of the voice in its different registers. The descriptions are much more clear and satisfactory than in ordinary books of physiology. The subject of stammering is also very well discussed. The practical part of the remainder of the work will only have novelty for the laity, for whom it is intended.

EYESIGHT, AND HOW TO CARE FOR IT. By GEO. C. HARLAN, M.D., Surgeon to Wills's Eye Hospital, etc. Health Primer Series, No. 4. Philadelphia: Lindsay & Blakiston. 12mo, pp. 139.

We may fairly rank this little work as one of the best of the Health Primer Series. It is written in a popular, untechnical style, and conveys much desirable information to the general reader. The chapter on the "Practical Suggestions for the Care of the Eyes" is especially worthy of commendation, characterized as it is by the practical good sense with which it abounds. We heartily commend the enterprise of the publishers in providing for the growing demand for works of this class.

APPLICATION DES SCIENCES À LA MÉDECINE. Par le DR. EDOUARD FOURNIÉ. Paris, 1878.

We have read this stout octavo volume with much interest. It is more valuable than the title at first suggests. By "la médecine" the author means therapeutics, and the sciences of which he especially traces the application are anatomy and physiology, physics, chemistry, botany, and zoölogy. As the method is historical, and the author aims to cover the whole ground, the work becomes a succinct history of the development of medical science from Hippocrates to last year. Dr. Fournié is so well informed, and so skilful a writer, that he has made a book alike interesting and instructive, particularly in two directions. In the first place, we suppose very few physicians have a clear conception of the steps by which the earliest empirical treatment of disease has developed through twenty-three centuries into the complex science of to-day. This volume gives a clear and sufficiently detailed history of that advance, with a very well-proportioned emphasis on the more important epochs. Whoever the reader may be, we venture to say he will be astonished at the antiquity of some things which he supposed modern, and at the recent introduction of some of his most familiar ideas. The second great utility of the volume is, that it offers a compendious view of all the established resources of the healing art. Medicine is necessarily so much divided into specialties of study and of practice, that no man can have personal familiarity with all the means of exploration, registration, and treatment which so rapidly come into use. It is therefore urgently necessary that from time to time some competent eye survey the whole field and give the profession a full report of what is doing in all departments. Dr. Fournié has done this in a most satisfactory manner, with just enough of fulness and of brevity. The illustrations are numerous and good.

If a critic were necessarily a fault-finder, we might say something of the author's rather *ex cathedra* tone when he passes judgment, of the excellent reasons he generally finds for considering the contributions of Germany either unimportant or not original, and the complacency with which he settles several discussions of contested points by quoting from his own previous works. But these things are occasional, and lie so much aside from the real business of the book, that they rather serve to flavor the dryness of the narrative than to impair its very great value.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 8, 1879.

DR. JOSEPH W. HOWE, VICE-PRESIDENT, IN THE CHAIR.

REMARKABLE PUNCTATE FRACTURE OF SKULL.

DR. R. E. VAN GIESEN, of Brooklyn, N. Y., presented a patient who had sustained a remarkable punctate fracture of the skull, and gave the following history:

Robert S., æt. 45, stout muscular man of good habits, ship-carpenter by trade, fell, June 21, 1879, from a ladder, striking the left side of the head against a galvanized spike four and three-eighths inches long by five-sixteenths of an inch in diameter, which projected from an inch plank three and three-eighths inches. The spike penetrated the whole of its free length flush up to the side of the skull, entering at a point directly opposite the incisura intertragica, half an inch below level of the external canthus, and five-eighths of an inch posterior to external canthus, near the junction of zygomatic process of temporal with the malar bone. The latter was dislocated downward and forward, and was freely movable. The sight of the left eye was lost immediately upon reception of the injury—at least there was no vision upon examination some fifteen minutes after the accident. A probe passed carefully into the wound, after slight hemorrhage was controlled with lumps of ice, passed three inches in nearly a horizontal line; and the little finger one and three-fourth inches, where spicula of bone could be felt; and, slowly withdrawing the same, the malar could be moved by pressing forward and downward. It is probable that the spike, in its onward progress, entered the sphenomaxillary fossa, wounding the optic nerve, and perhaps piercing the antrum of Highmore, though repeated probing at the time of the injury and many times since has failed to enter that cavity. There was no bleeding from the ear or mouth, and but slight bleeding from the nose.

It seemed hardly possible that a wound with such an instrument, penetrating to such a depth in the direction described, could fail of seriously endangering the brain; and the progress of the case was awaited with the utmost anxiety. Cold-water dressings were applied, and a brisk purgative of compound jalap powder.

22d.—There is great chemosis of the left eye; swelling and infiltration of surrounding tissues considerable; free scarifications of conjunctiva; wound gently syringed with a two per cent. solution of carbolic acid in tepid water.

June 30th, ninth day from accident, patient has not

had a single untoward symptom. He has been kept on low diet, and saline cathartics given every second day. Swelling is still very great, and discharge of pus very profuse. A few very small spicula of bone have been discharged.

July 10th.—On syringing, water comes freely through the nose; left side, there is fluctuation near angle of lower jaw.

July 12th.—Counter-opening made at that point; free discharge of pus; water and air can be made to come through nose and the counter-opening.

July 25th.—Fluctuation half an inch under left eye; opening made; all openings communicate with each other, as air can be made to issue from them by holding nose and forcibly blowing.

July 27th.—Discharge of pus from all openings slight. Keep all open by tents, and syringe three times daily as before.

August 5th.—Suppuration almost none; allowed counter-openings to heal; keep main wound open. Patient at work, feeling well.

October 8th.—Original wound nearly closed; probe enters about one and a half inches; water still runs from left nostril on syringing.

The patient was kindly examined by Dr. D. B. St. John Roosa, who reports condition of left eye as follows: Iris healthy, lens and vitreous clear. Fundus: arteries thread-like, veins smaller than normal; the whole constituting white atrophy of the disk.

The right eye is normal.

The condition of malar bone at time of presentation was slightly below level of its fellow, and firmly united.

CANCER OF THE LUNG.

DR. VAN GIESEN also exhibited portions of the lung and liver of a young man with the following history:

July 1, 1879.—Called to see Geo. S. J., *æt.* 30. Good family history, free from tubercular or cancerous taint.

His general appearance is that of fair health. Some months ago was confined to his bed with a severe illness, diagnosed by the attending physician as pleurisy and organic disease of the heart. He recovered partially, and has been at work as a clerk until within the past few weeks, but has never felt entirely well. He now complains of severe pain on the left side anteriorly, shooting through to the shoulder-blade, increased at night; and a dry, hacking cough in the morning, entirely devoid of expectoration; the face is usually bluish and swollen or puffed in the morning. There are bluish spots on the left side of chest anteriorly. The left arm is slightly oedematous and painful. The temperature is normal as well as the pulse.

July 2d.—Urine carefully examined, and found normal. The patient came to office, and the chest was carefully examined. The left infra-clavicular region is very dull on percussion. Same region posteriorly much clearer, but less than normal. Left side measures nearly an inch and a half more than the right. There is slight impulse on infra-clavicular left side.

Apex of right lung presents decided dullness, but much less marked than on the left side; change in position of the patient does not affect the area of dullness.

The radial arteries beat with about the same impulse. There is no decided enlargement of glands of neck or axilla; appetite good; no sweating at night. The treatment was directed to the allaying of the pain.

July 5th.—Dr. E. G. JANEWAY saw the case in consultation, and, after a very careful and prolonged examination, pronounced it one of malignant growth of the lung, perhaps an aneurism. At this time the chest was punctured in two places with a hypodermic needle without obtaining any fluid. The impulse under the clavicle was barely perceptible, and a simple device was resorted to to render it apparent. A moderate-sized potato was cut in two; on the convex surface was stuck a long darning-needle, on the remaining extremity was fastened a small strip of paper standing at right angles to the needle. This was placed over the suspected pulsation, and the paper brought in a line parallel with the window-sash; by sighting across the paper to the window the pulsations could be readily seen and measured.

July 7th.—Saw patient again and ordered infus. digitalis, and as he was desirous of a change, recommended him to go to his father's residence at Bay Shore, Long Island. He here passed into the hands of Dr. Vandewater of that place, and I did not see him again until Aug. 30th, when I found the area of dullness very much increased over both lungs. Oedema of both right and left arm; more decided impulse infra-clavicular; increase of dullness over right apex. Nearly whole of left lung impervious to air.

The left pupil is dilated and the eyeball protruding.

Sept. 11th.—After several severe attacks of dyspnoea the patient became quiet, and died without pain or suffering at 3 P.M. Dr. Vandewater informed me that the protrusion of the eyeball became very prominent a few days before death, and that blueness of the face and upper extremities was almost constant.

Sept. 14th.—Post-mortem examination, which was kindly made by Dr. Wm. H. Porter. The body is well nourished. On proceeding to open the chest the initial incision was immediately followed by a slight flow of thick, milky juice, and there was found a hard, milkish white deposit, near the sterno-clavicular articulation, gluing the muscles to the chest-wall in that region. The bones at this point were very much softened, and broke down easily under pressure between the thumb and finger.

After freeing the lower portion of the costal cartilages, and endeavoring to raise the sternum in the usual manner, we found it adherent for about two-thirds of its length to a new growth, firm and hard in consistence; tracing this latter with the hand, it was found to involve nearly the whole of the left lung, strongly adherent to the chest-walls, and to the pericardium and the lower portion of the thoracic cavity; left side contained about ten ounces of liquid of a deep beer color, and numerous flakes of fibrin of the same color.

After loosening the growth, an incision fully an inch and three-quarters deep was made through the tumor over the heart, before the pericardium was penetrated. The heart was found small and contracted, covered with villous exudation, and the pericardium lined with the same material.

The pericardium contained a small amount of liquid, and was not anywhere adherent to the heart. The pericarditis is evidently of a remote date. The left lung was now entirely removed. There was found but little healthy pulmonary tissue not invaded by the cancerous growth.

Right lung presented the same appearance in a much less degree, the apex being the part chiefly affected. Right pleural cavity contained some twelve ounces of fluid. No adhesions except at the point of cancerous deposit. Liver shows a few nodules of secondary deposit.

Kidneys hyperæmic. Head not examined; the protrusion of eyeball probably due to deposit in cellulose of orbit. The physical signs are entirely explained by the pathological appearances; the impulse by nearly two inches of dense solid matter lying directly over the heart. The effusion comparatively small in amount, was probably present when the hypodermic punctures were made, but the level of the fluid was below the point of insertion of the needle.

In conclusion, the doctor wished to refer the specimen to the microscopical committee, which was done accordingly.

Dr. LANGE remarked that in a part of Saxony there had been almost an epidemic of cancer of the lung, more than a dozen persons being attacked.

BONY TUMOR OF COCCYX.

Dr. Post exhibited a bony and pigmentary mass which had been removed by operation from an unmarried lady, twenty-five years of age, who had bruised the lower part of her spine by a fall two years previously. A small abscess formed, which after a time became apparently healed, but discharged matter at each menstrual period. When Dr. Post saw her there was a bony prominence over the coccyx. This prominence was excised and the sinus laid open, after which the wound healed.

LUPUS OF FACE REMOVED BY EXCISION—TRACHEOTOMY WITHOUT THE TUBE.

Dr. Post also presented a drawing of an enormous lupus of the face, upon which he had performed an operation of excision. The patient was a German woman, sixty-one years of age, who was an inmate of the Presbyterian Hospital. She had the disease in the region of the nose for several years. At the time she entered the hospital the whole nasal pyramid had been swept away, and the ulceration had involved the integument at the root of the nose and between the eyes, upon the forehead, and four-fifths of the upper portion of the upper lip. As a precautionary measure against the escape of blood into the trachea, Dr. Post performed tracheotomy without a tube, after the manner proposed by Dr. H. A. Martin, of Boston (*Amer. Med. Association Trans.*, 1878). The patient was fat, had a thick neck, and the subcutaneous vessels were large and numerous. Dr. Post stated in passing that the method of Martin maintained a wider opening than when the tube was used; that there was no irritation from the presence of the foreign body; and lastly, that there was no obstruction from the presence of mucus. From his experience in this case he was led to believe that wearing the tracheal tube after tracheotomy will be placed in the same category as that of wearing the catheter after urethrotomy. He remembered one case in that connection which had its bearing on the question of wearing the tube after tracheotomy. Many years ago he performed tracheotomy for the temporary relief of malignant disease of the throat. The tube had been worn for a considerable period, and on its removal there was a well-marked ulceration caused by pressure.

To return to the patient with lupus, Dr. Post stated that as soon as he had opened the trachea he crowded a large piece of sponge into the mouth, cutting off all communication with the trachea. It was his intention to use Paquelin's thermo-cautery, but unfortunately the india-rubber bag burst and he was compelled to use the knife. He began by making an incision below the margin of the diseased growth,

thence on either side of the cheek to the inner canthi. The diseased portions on the latter situation were removed by the scissors. After completing the operation, which was a tedious and bloody one, the wound was dressed with shreds of lint and collodion. A little incident occurred a day or two after the operation which was worthy of note. The patient was rather suddenly attacked with emphysema, due to the entrance of air into the subcutaneous cellular tissue of the neck. This was promptly arrested by reopening the wound over the trachea. He stated that should the present operation be successful it was his intention of constructing a new nose from some other part of the body, taking the ring finger for a skeleton basis.

INTRA-MURAL FIBROID OF UTERUS.

He also exhibited a third specimen. This consisted of an intra-mural fibroid of the uterus, weighing twenty-two ounces, removed by operation from a maiden lady, who was sent to him from Delaware County by Dr. McNaughton. About six months since, the patient suffered from retention of urine; and the family physician, examining for the cause of the trouble, discovered a fibroid tumor projecting into the vagina. When Dr. Post saw her, the tumor extended to the vulva and was found to be attached to the posterior wall of the uterus, the posterior lip of the organ being lost in the growth. There was very little hemorrhage present at any time. The uterine probe passed up a distance of four inches beyond the anterior lip of the cervix uteri. She was placed upon ergot for some time with a view of bringing down the growth. She progressed very satisfactorily until a few days before the operation, when she began to droop and show some signs of blood-poisoning. On examination, the tumor was found of a livid complexion, and giving rise to a fetid discharge. It was quite evident decomposition was going on, and that there was a necessity for immediate operation. At the time of the operation the lower extremity of the tumor extended through the labia, filled up the vagina, and was about seven inches in length. The mass which protruded was excised first, and then the stump was drawn down, different portions being excised as they were brought into view, until, finally, the vaginal portion was excised. Then grasping the stump, he endeavored to detach it with the finger and then made use of Thomas's serrated spoon, and succeeded finally in removing the whole mass. No unpleasant symptom followed the operation, and the patient made a rapid recovery.

INTESTINAL CALCULUS—INVAGINATION OF THE BOWEL—STERCORACEOUS VOMITING—RECOVERY.

Dr. C. A. LEALE presented an intestinal calculus discharged by a lady 79 years old. It had its origin as a biliary calculus which was passed from the gall-bladder, became lodged at the ileo-cæcum, where from $3\frac{1}{2}$ inches in circumference, it was increased to $4\frac{1}{4}$ inches by concentric layers of stercoraceous matter, and where from inability to be passed it produced an invagination of the bowel, until the presenting portion could be felt within four inches of the anus; digital dilatation gave it an exit from the small into the large intestine, from whence it was removed by bimanual vagino-rectal manipulation, forty-five days after entering the intestinal canal. The patient being relieved by stercoraceous vomiting every three or four days, as during the entire time only one movement of the bowels occurred by rectum, the return of the invaginated portion by in-

jections of carbonic acid water was soon followed by entire freedom from pain, and recovery.

He gave the detailed history of the case as follows:

Mrs. Q—, *æt.* 79 years, for over thirty years resided in a miasmatic region of Pennsylvania; has had malarial fevers, and for more than the past twenty years has two or three times a year suffered severely from attacks of bilious colic. She has been under my observation for the past seven years, and during that time has, about once every four months, had a violent attack of either bilious or intestinal colic, to be followed by persistent jaundice, which appropriate treatment (generally small doses of podophyllin) would relieve. About the 20th August, while in the country, Mrs. Q— had the most violent attack that she ever experienced, and described her pain as though a portion of her liver had been torn off. The pain lasted nearly an entire day, to be followed by *dysentery*, great tenesmus, and tormina, lasting for the next six weeks. September 1st, Mrs. Q— returned to the city, and in a few days was seen by me. She was then jaundiced, and had complete *obstruction* of the bowels, violent tenesmus, and occasional discharge of about half a drachm of bloody mucus without a trace of fecal matter.

On the 10th of September the accumulation within the intestines caused great distress and violent peristaltic action of the bowels, to control which opium was given in one-grain doses, hoping thereby that at the same time it would produce its opposite effect and relieve constipation. Clysters of warm water had frequently been resorted to, and to relieve tenesmus laudanum added. All efforts to overcome the obstruction by means of the long elastic rectal tube failed, it being impossible to pass it up to the sigmoid flexure. On September 1st the pain could be localized at the ileo-cæcal valve, and it gradually changed along the course of the ascending transverse and descending colon until September 15th, when it was located at the sigmoid flexure. As had occasionally been done, a mild solution of the sulphate of magnesia was given, to, if possible, liquefy the feces and pass the obstruction; but this only increased the peristaltic action, to be followed by distressing nausea and vomiting of the fecal contents of the small intestines. The vomiting of fecal matter was repeated every three or four days, each attack being followed by almost fatal prostration. This condition continued until September 25th, when a manual exploration of the rectum was again made, after again failing to pass the bougie—at this time the pain was localized at the upper part of the rectum. The patient was placed in the position *à la vache*, and the end of the finger could distinctly feel the presenting *invaginated portion of the bowel*, where the cause of the failure to pass the bougie was made apparent, as the portion presented as a bulging, elongated patulous os, through which even a small No. 8 silver catheter failed to pass, but by bimanual examination, one hand in rectum and one on abdomen, the finger was made to pass through the soft, velvety congested presenting part, and dilatation gradually accomplished, when feces followed the withdrawal of the finger, and fully two quarts of pasty feces were voided; the first and only passage from the small intestines for thirty-six days. In a few hours the obstruction again was apparent, and fecal vomiting recurred at intervals of two or three days.

At no time did the temperature go above $101\frac{1}{2}$ F., and the symptoms of exhaustion gradually became more alarming. The constant desire to have a passage, and the violent tenesmus being relieved by opium, either by mouth or rectum, in small doses, as

one grain at times, produced six or eight hours of sleep. Sept. 26th.—She was much very exhausted and only kept alive on frequently repeated draughts of champagne. Sept. 28th.—Violent fecal vomiting and almost fatal prostration; to facilitate the cleansing of the stomach, warm water was plentifully given until a thorough washing of the stomach had been accomplished.

During the entire time Mrs. Q— was given articles of diet most rapidly to be assimilated, and which would form as little effete matter as possible, and the anti-peristaltic action of the bowels encouraged as often as the strength of the patient would justify, by means of saline cathartics, to be followed by copious draughts of warm water to relieve the stomach of its intensely offensive contents. Each time that the stercoraceous matter passed up into the stomach, the extreme disgust, fecal eructations of gas, and sense of weight gave a desire to vomit; and, although the patient dreaded to vomit, she eagerly drank the warm water to facilitate throwing off the offensive contents of the stomach.

October 1st.—She was seen in consultation by Dr. Austin Flint. No change occurred; the same treatment continued to relieve bowels by stomach and vomiting, and the occasional saline cathartic to soften the contents of the bowels, and opium *p. r. n.*

At 9½ A.M., October 6th, I received a telegram stating that a sudden change had occurred, and that Mrs. Q— was dying. I was soon at her bedside, and found that she had had a convulsion and intense pain at the sigmoid flexure of the colon. She was then so much exhausted that her pulse for some time was imperceptible; but, by the frequent administration of champagne, she rallied sufficiently on the following day to admit of another rectal exploration, when this hardened mass was felt just protruding through the strictured presenting part. By bimanual, rectal, and vaginal manipulation, it was easily removed, after breaking in two pieces, and the cause of the convulsion was by reflex irritation as it passed through the strictured portion. It is composed of a hardened, dark brown, circular, homogeneous mass, four and one-fourth inches in circumference, and two and one-half inches long, weighing one hundred and seventy grains, having a very strong fecal odor, and enclosing a circular nucleus three and one-half inches in circumference, which was passed from the gall-bladder, the formation around the original nucleus being in concentric layers of stercoraceous matter, each about half a line in thickness, and which, August 20th, became lodged at the ileo-cæcal valve, protruding that portion through the large intestines until the invaginated portion reached within five inches of the anus, when digital dilatation completed its exit from the small intestines, and from which portion of the rectum it was removed by bimanual vagino-rectal manipulation, since which time the aged patient has been free from pain, and a copious injection of carbonic acid water has returned the bowel, and placed her in a condition for a rapid recovery.

Dr. P. C. COLE examined the specimen microscopically, and found it to consist of cholesterine, with a large mass of granular matter colored with biliverdin, the whole mass arranged in concentric layers, and very fragile.

In conclusion, Dr. Leale made the following remarks: In man, the unusual occurrence of intestinal calculi may be concluded when we search in vain for a single illustration in the last medical volume, part ii., of the History of the War, which several of us have

just received, and contains a record of 1,739,135 cases of diarrhoea and dysentery, with 44,558 deaths, besides quotations from all the attainable authorities, making probably the most exhaustive work (a quarto of over 850 folios) ever published; and yet, not a single instance is cited where the cause of the invagination and dysentery is due to the presence of an intestinal calculus, and when, as shown in the history now recorded, these conditions can exist as a provoking cause for both these serious irritations of the intestinal canal, and causing both invagination and weeks of dysenteric discharge below the seat of the obstruction.

Intestinal calculi are not uncommon in the horse, and are a frequent cause of colic and irritation of the bowels. According to Youatt, they are generally found in the caecum or colon, varying in size from a few grains to several pounds, and shaped in accordance with the nucleus around which they increase; and, in regard to their treatment, Prof. Morton, R.V.C., in his essay on "Calculous Concretions," states that little can be done to procure their expulsion, or even to determine their existence; and that, although some may be expelled, others become so firmly impacted as to resist all medicinal means of withdrawal, and a few have broken their way through the parietes of the rectum, and lodged in the abdominal cavity.

According to Mr. Percival, in his "Elementary Lectures on the Veterinary Art," these calculi may be the cause of fearful destruction of the contiguous soft parts, and consequently of the most intense pain.

A GUMMY TUMOR OF THE PONS AND CRUS, WITH DISSEMINATED, CORTICAL, AND MEDULLA LESIONS OF SPECIFIC NATURE, CAUSING PARALYSIS OF THE RIGHT THIRD NERVE, TRIGEMINAL NEURALGIA, AND EPILEPSY.*

Dr. AMDOX presented a specimen of above, with the following history:

Wielow, aet. 33; for two years had suffered from amenorrhoea, neuralgia in the upper two branches of both fifth nerves, pigmentation of the skin in neuralgic area, and epileptic attacks with a nasal aura. Later in the disease she developed anorexia, slow and difficult articulation and deglutition, vomiting and constipation. All these symptoms went away under mixed treatment, and patient was discharged cured.

Recurrence, however, occurred in three months with greater severity, and patient died comatose, with all symptoms narrated above.

At the autopsy there were found, besides traces of old syphilitic inflammation in the liver and a parenchymatous nephritis, numerous brain lesions, viz.: yellowish, nodular deposits in each anterior perforated space, and, at the commencement of the fissure of Sylvius, a gummy tumor replacing the right third nerve and invading the pons and crus, and a grayish, translucent deposit on the posterior surface of the medulla oblongata.

The lesions everywhere seemed to be of vascular origin.

The tumor itself, connected with the basilar artery, consisted of small round cells with no intercellular substance. The vessels in the pia mater show marked exudation of new cells into the perivascular spaces and surrounding cortex, and the medulla also shows a dense, small-celled infiltration into the region of the lower sensory root of the fifth nerve.

The interesting points are, whether the deposit in the anterior perforated spaces caused the nasal aura,

and whether the lesion of the lower fifth nucleus and root does not tend to show that that part gives origin to the upper branches of the fifth nerve.

THE PHILADELPHIA ACADEMY OF NATURAL SCIENCES.

MICROSCOPICAL AND BIOLOGICAL SECTION.

Regular Meeting on October 4, 1879.

DR. KENDERDIVE, PRESIDENT, IN THE CHAIR.

(Reported for THE MEDICAL RECORD.)

THE HISTOLOGY OF TUMORS.

DR. CARL SEILER, the lecturer for the evening, spoke at length upon the subject of the "Histology of Tumors." He said that he did not wish to enter too fully or too scientifically into the histology of tumors, as there is so much difference of opinion among students in regard to the morbid processes involved, and because he desired to adapt his remarks to the comprehension of all the audience.

All tumors were formerly divided into sarcomata and carcinomata. They are still so named, but the sarcomata, or *fleshy tumors*, were considered harmless, while the carcinomata, or cancerous, were held to be malignant. The lecturer then said that there were many of the sarcomata as malignant as the carcinomata, the malignancy depending in great measure upon the position of the tumor and the proneness to secondary deposits of tumors in distant organs. To illustrate this point, he called attention to the fact lately brought forward by Dr. S. W. Gross, of Philadelphia, that the round and spindle-celled sarcoma of the long bones are by far the most malignant tumors, and that they usually formed secondary deposits in the lungs, to which the patient succumbs. The same form of tumor in connection with other bones was not to be considered very malignant, and could be removed by an operation with considerable hope of saving life.

Tumors are at the present day divided into: first, those formed of *connective-tissue* elements in various stages of development; and second, those formed of *epithelial* structures. The presence of the so-called *cancer-cell* or *spindle-cell* was formerly regarded as the certain evidence of a malignant growth, and until a period within the last ten years was so taught in our medical schools. This spindle-cell is also found in normal connective tissues, in embryonic tissues, cicatrices, etc.; and although such distinguished histologists as Virchow, Billroth, and Rokitansky have endeavored to find a special cell indicative of the malignant nature of cancer, they have never succeeded. All are agreed that cancer should not be regarded as anything distinct, and that its cell-elements are either identical with the embryonic or with the fully developed tissues. The simplest form of tumor is found in *granulating tissue*, or what is known as *raw flesh*. When we make a section of such a neoplasm we find that the cells present the simple round appearance analogous to the embryonic connective-tissue cell, and precisely identical with the cells of the round-celled sarcoma. A similarity also exists in the blood-channels of the round-celled sarcoma and of embryonic tissue, they being without walls. By throwing out prolongations, and by contraction of the embryonic cell-condition, the connective-tissue cells are formed, and in granulating surfaces which advance to the stage of healing, we find the cicatrix made up of or containing the spindle-cells. These two forms of cells,

* Service of Dr. W. H. Draper, New York Hospital.

the one as found in simple granulating surfaces as well as in the round-celled sarcoma, the other as found in connective tissue and in the spindle-celled cancer, have the power of infecting the tissues. In this consists the special malignant characteristic. The apparent presence of the round cells in the spindle-celled tumors is owing to the transverse sections of the interlacing spindle-cells, and is always so regarded.

The nature and character of the lipoma or fatty tumor, the osteoma, and various tumors formed by the admixture of these elements, were referred to by the lecturer. The fibroma was described as a tumor which in itself did not produce any dangerous symptoms, but might, indirectly, by its position. Dr. Seiler was of the opinion that the recurrent fibroma of the English surgeons must be looked upon as an encapsulated spindle-celled sarcoma, and the recurrence *in loco* of the tumors must be explained by the presence of tumor-elements in the tissues outside of the capsule, which elements have the power of reproducing the neoplasm.

The second class of tumors, the epithelial, were then considered. By irritation of the epithelial elements, or when the nutritive processes are actively stimulated, we have an undue development of these cells outward, constituting the form of tumor known as the papilloma or wart, the simplest form of epithelial tumor. By the same process, limited by the thick and hardened epidermal layers at a later period of life, the cell-growth extends inward in the direction of the least resistance, and the form of tumor known as the epithelioma results.

The adenomata, or glandular tumors present the appearance of increased glandular elements. The proliferating epithelial cells may, however, fill up and enlarge the acini to such an extent that finally the limiting membrane is broken through, and the cells continue to grow into the adjacent connective tissue, where we find nests of proliferating cells, usually of an elliptical form from being pushed forward. When the connective tissue predominates, or is greatly increased in amount, a hard scirrhous cancer will result. If the connective tissue fails to increase, and the epithelial cells develop to such a degree as to wither or overbalance it, then these cells, also breaking down from pressure, etc., form the soft variety, of cancerous tumor. In conclusion, the lecturer said that the chief point which he desired to bring before the gentlemen of the Academy was, that there is no such thing as a *cancer-cell*, and that the question whether a cell is malignant or not, depends upon the infiltration of the new cell-growth, the position of the cell-growth, secondary deposits, etc., etc.

Dr. ALFRED REED gave as a reason why the lungs are a favorite seat of secondary cancerous deposits, that they are formed by the same germinal layer of the embryo as the bones.

In reply, Dr. Seiler said that tumors not originally situated in bones form secondary deposits in the lungs, and, on the other hand, tumors of the bones form secondary deposits in other internal organs, and especially in glandular organs. He further said that it needed but a very few of the tumor elements carried to a distant point by either the circulation of the blood, or, as is more frequently the case, by the lymphatic circulation, in order to start a new point of development. In proof of this the lecturer related some experiments lately performed in Germany, in the course of which a few cartilage cells taken from a cartilaginous tumor were engrafted upon the cornea of a rabbit, and also in the muscular tissue of another

animal of the same species, which formed the starting-point for similar growths to that from which they had been originally taken.

The lecture was profusely illustrated by diagrams, and by a large number of slides showing the different varieties of tumors and their histological details.

THE NEW YORK ACADEMY OF MEDICINE.

OBSTETRIC SECTION.

Stated Meeting, October 30, 1879.

Dr. SALVATORE CARO, CHAIRMAN.

The Section was called to order, and the minutes of the last stated meeting were read by the Secretary, Dr. HENRY E. CRAMPTON.

ABSCESS OF THE ABDOMINAL WALLS.

THE CHAIRMAN then read a paper on the above subject, in which he gave the history of an interesting case that involved important points in diagnosis. The patient was aged fifty-eight years, a widow, and the mother of several children. In 1878, September 29th, she, for the first time, occasionally felt a dull pain in the left umbilical region. She suffered from habitual constipation, and had a large, flabby abdomen. At that time there was a nodule about the size of a walnut, painful to the touch, and situated in the substance of the left transversalis muscle, immediately over a portion of the descending colon, which was distended with feces. It could be readily grasped, on account of the relaxed condition of the abdominal walls. The bowels were emptied by cathartic medicine, and the patient was at once relieved. They again became constipated, and the same trouble returned; they were again emptied, but the swelling increased in size, was painful to the touch, and smooth on its surface. That was in February, 1879, when Drs. P. V. White and James L. Little saw the case in consultation. There was slight enlargement of the superficial veins. The tumor was large; it was tympanitic on percussion; there was no distinct sense of fluctuation; there was no marked heat. Dr. Caro inclined to the opinion that it was an abscess. Drs. White and Little thought it was a malignant intra-abdominal growth. All consented to the introduction of a hypodermic needle. A needle was introduced, and passed in its entire length, when the end moved freely as though in a cavity. The piston was then drawn, and the barrel was filled with a purulent fluid, exceedingly offensive. The question then arose, when should the operation for the removal of the pus be performed, and it was decided to cut for it at once. Accordingly an incision, two inches in length, was made six inches below the umbilicus and eight inches from the median line. The dissection was carried carefully down about an inch, when a sac was reached, which was opened, and a large wash-basin full of decomposing and exceedingly fetid pus was evacuated. The sack was washed out with carbolized water, and a plug of lint left in the wound. In the evening the dressings were found saturated with pus; they were removed, and about one quart of pus was evacuated. The sac was washed out regularly; the discharge soon began to diminish in quantity, and quickly presented a healthy appearance, and on the 27th of February the woman was regarded as cured.

On March 2d she took cold, and on the 3d she had

a severe chill, followed by fever and pain in the region where the opening was made in evacuating the former abscess. Her pulse was 140, and temperature $103\frac{1}{2}^{\circ}$ F. She coughed, and there was a tendency to vomiting. A poultice was applied to the painful part.

March 4th. — Pulse, 100; temperature, 102° F. Removed the poultice; tore open the old cicatrix, and about one pint of offensive pus was evacuated. The sac was treated as before, and on the 15th the patient was again discharged as cured.

The case was interesting on account of the exceptional lack of symptoms. Early opening of an abscess when the presence of matter can be ascertained was advocated, and opening by means of an incision. Dr. Caro also regarded it as desirable that the injection of the cavity should be made by some instrument by which the fluid could be removed without removing the nozzle of the syringe. He thought the cause of the abscess in this case was the irritation produced by the intestine, distended with hardened feces, rubbing against the abdominal wall. He dwelt at some length on the pathological process of the formation of pus.

Dr. J. LEWIS SMITH remarked, regarding abscess in the abdominal wall in children, that there were two kinds: first, those in which the cause was located in the intestine, and produced by round worms; and second, those in which there was a lodgment of some substance in the appendix vermiformis, and giving rise to abscess. It occurred to him, on account of the great offensiveness and the great quantity of discharge in Dr. Caro's case, that the cause might be within the intestine, and that a piece of feculent matter lying in one of the pouches of the colon had excited irritation and inflammation. He favored the early opening of abscesses seated in the walls of cavities, whether pleuritic or abdominal, and referred to cases in which delay had permitted them to open into the pleural cavity, give rise to empyema, and cause death. The strength of the solution of carbolic acid he usually employed for washing out such cavities was 1 to 40.

Dr. MERRILL remarked that the case which he reported to the Section at a former meeting, and which gave rise to the present paper, was one of pelvic abscess, resulting from cellulitis, and terminating in rupture internally and general peritonitis, and death. He asked regarding the propriety of opening such abscesses early, either through the abdominal wall or through the vagina.

Dr. FORDYCE BARKER replied that his rule was to aspirate a pelvic abscess as soon as he could detect the slightest evidence of fluctuation or even a suspicion of it. In several cases he had drawn out only a drachm or two of serum before the formation of an abscess, and had found that the process of cure had been very much promoted by the procedure. Formerly he opened through the vaginal walls in some cases, but latterly he had found that the aspirator accomplished all that was necessary; and especially was that true regarding pelvic cellulitis occurring during the puerperal period. In the early period of these cases the aspirator was sufficient, but in the latter stages of some of the cases the aspirator might not give a sufficiently free outlet for the fluid. If there were no constitutional symptoms present, use the aspirator at once; no harm came from its use, and he had never had occasion to regret using it.

Dr. J. C. PETERS referred to the occurrence of abscesses in the recti muscles of the abdomen. He was not able to understand how constipation could pro-

duce abscess in the abdominal wall without exciting peritonitis. The peritonitis, however, might be local, and give rise to adhesions. Abscesses in the recti muscles were usually regarded, at first, as cases of peritonitis.

After remarks by Drs. SELL, CHADSEY, and HANKS, the paper, on motion, was referred to the Academy, and the Section then adjourned.

Correspondence.

"STATE MEDICINE."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In reading the RECORD for November 8, 1879, we find an article on State Medicine, by Prof. Henry M. Lyman, in which some statements are made which, if logically carried out to their legitimate conclusions, would, we think, render it practically impossible to prevent the spreading of any epidemic by the action of boards of health, or other local or State organizations.

Among other statements, Prof. Lyman says that "The old doctrine that every man's house is his castle, is as true in matters pertaining to health, as it is in affairs of politics or religion. Government has no more right to compel a man to make his home healthy, than it has to compel him to make his home religious."

The glaring fallacy of the above statement is self-evident, from the fact that the two things mentioned are not comparable with each other.

The State cannot, nor indeed ought not, to interfere to compel a man to make his home religious, simply because scarcely any two men would agree as to what is meant by the term a religious home; hence, such legislation would be practically inoperative and impossible.

If, however, a man in exercising this so-called right to form a home, practises violations of the moral code, the strong arm of the law does interfere, and that very summarily, to protect the community from his evil deeds.

A similar principle underlies all legislation intended for the suppression of disease.

We deny absolutely that any man has either a legal or moral right to make his home unhealthy, simply because the relations of life are so intimately bound together in modern civilization, that he cannot do so without endangering the lives of others.

This principle of law also holds good in all other cases of similar character; if a man, for instance, owns a house in a city, he will not be allowed to burn it down. The law says to him, you have no right to destroy this property, even if it is your own, for the reason that in so doing you endanger the lives and property of those who live adjoining you.

But let us give one or two practical exemplifications of the working of these matters in every-day life.

The writer recently attended a family in which three (3) children were attacked with scarlet fever, from visiting a family who concealed the fact of scarlatina being present in their household; one of these children very narrowly escaped death, but they finally all recovered.

Another family, exposed in a similar manner through the same culpable suppression of the truth, were not

so fortunate; their only child, as the father expressed it, "was simply murdered."

If Prof. Lyman were in the position of the parent who lost his child in this way, we are inclined to think that he would materially modify his opinions, and might, perhaps, think that it would be well for the State to "compel a man to make his home healthy."

In another part of his paper, Prof. Lyman says that laws for the prevention of disease will be unpopular; this is, to a certain extent, true. We have ourselves seen the officers of the law hooted at, pelted with stones, and even forcibly resisted in the removal of nuisances from crowded localities; but this would scarcely be an argument for their retention.

In spite of all that has been said against legislation on the subject of health, we believe that intelligent citizens, as a class, are willing to submit to reasonable regulations, and even restrictions for the sake of the common good.

Believing as we do that the principles that Prof. Lyman advocates would render forcible all legislation on the subject of health, we have deemed them just subjects of criticism and comment.

ROBERT REYBURN, M.D.

WASHINGTON, D. C.

SUDDEN DEATH IN THORACENTESIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—We have read with interest Dr. G. E. Goodfellow's letter in your issue of November 15th, in which he narrates the history of a case of thoracentesis, in which great pain was experienced by the patient on three different occasions, at the point of introduction of the needle. On the first occasion "the act of puncture gave him no pain, but a few minutes after the needle was introduced he began to complain of pain in the region of the wound. It was also diffused over that side of the thorax. Moving the needle did not increase it greatly. One *gallon* of serum was withdrawn," etc. On the second occasion, "from the minute after the needle was inserted he complained of pain, which in a short time became most intense." "About fourteen ounces of fluid had been *very shortly* taken out, his complaints *steadily increasing* (italics ours), when a most alarming collapse came on," etc. On a third attempt, one week later, "the cavity as tense as before;" after less than an ounce had been withdrawn, "he complained a little, when an overwhelming . . . attack of pain supervened, and the same collapse came on," etc.

It will be observed in all three of these attempts that the pain did not attend the act of puncturing of the chest-wall, but came on after a certain amount of fluid had been withdrawn. The presumption seems to us strong that the "pain of the puncture, *par et simple*," had no connection whatever with the result. The probabilities seem to be that the needle came in contact with some of the viscera, lung, diaphragm, or pericardium after the withdrawal of a certain amount of fluid, and that the intensity and *diffusion* of the pain, and the subsequent collapse, are to be thus explained.

Dr. Goodfellow does not state the site of the puncture nor the depth to which the needle was inserted. Which one of the above-mentioned viscera may have been involved, he can judge better than we can. In our own limited experience with the operation, we have not found it easy to avoid touching deeper-lying viscera, and have a very disagreeable and vivid recollection of the sensation communicated to the hand

holding the needle by the grazing of what was probably the lung against its point.

In Dr. Goodfellow's case the patient had been sieg four months. If during this four months the lung had been retracted, it is reasonable to suppose that its expansion would be difficult, and the compensatory forcing up of the diaphragm and forcing over of the heart to fill the potential vacuum caused by the withdrawal of the fluid would be very considerable. These considerations are, of course, of little weight as applied to the third attempt, when only about an ounce of fluid was withdrawn. The location and depth of the punctures are the all-important points in determining the plausibility of the explanation of the case which we offer.

Very truly yours,

R. VAN SANTVOORD, M.D.

66 WEST ELEVENTH STREET,
Nov. 15, 1879.

PHARMACOPŒIAL REMEDIES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Among the proprietary, trade-marked, and patented medicines largely used by some, even eminent physicians, are: McMunn's Elixir, Chlorodyne, and Winslow's Soothing Syrup.

The composition and mode of manufacture of the first has long been known (see United States Dispensatory, 13th edition, p. 1470), as the formula was found among the papers of the late pharmacist Mr. Chilton, who is said to have received it from the proprietor. It is merely a watery solution of the extract of opium, also deprived of the odorous and other injurious ingredients of the drug by means of ether. The ether extracts the narcotina and the noxious odorous matter of opium, which are probably the most offensive and least useful constituents. The place of the Elixir is now, and has long been well supplied by the Tinctura opii deodorata of the U. S. P., which Wood and Bache think should be called Infusum opii deodoratum, or some other title expressive of the fact that it is essentially a watery solution of the extract of opium, alcohol being used in no degree as a menstruum, but merely as a preservative.

It is barely possible that loyal physicians may consistently use such proprietary medicines at their first introduction; but they should quickly substitute their own prescriptions therefor, which, doubtless, if aided by a good chemist, will be far more scientific and useful than the patented and advertised article of any mercenary proprietor.

Chlorodyne is still largely prescribed by physicians who should know better than to use a remedy which has all the bad effects of the worst preparations of opium. Squire (see Companion to the British Pharmacopœia) gives the formula for this complex and dangerous medicine, viz.: Chloroform, 4 oz.; ether, 1 oz.; rectified spirit, 4 oz.; molasses, 4 oz.; extract of liquorice, 2½ oz.; muriate of morphia, 8 grs.; oil of peppermint, 16 minims; syrup, 17½ oz.; prussic acid (2 per cent.), 2 oz. To combine them, dissolve the muriate of morphia and oil of peppermint in the rectified spirit; then mix the chloroform and ether with this solution; dissolve the extract of liquorice in the syrup, and add the molasses. Then shake the two solutions together, and add the prussic acid, with some tincture of capsicum.

The imported article is very dear indeed; far out of proportion to its real value and usefulness. Any pill of opium and cannabis indica with capsicum is equally good; the various well-known combinations

of the solutions of morphine with prussic acid or aqua laurocerasi are equally manageable; and the writer from the very first used, instead of the patented English article, with equally good, and even better results, a combination of chloroform, tinct. cannabis indica, solution of morphine, prussic acid, or cherry-laurel water, and syrup of ginger, with or without capsicum.

PHARMACOPŒIA.

MEDICAL ETHICS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In the account of the last meeting of the County Medical Society, in your issue of Nov. 15th, it is stated that the Censors reported that the Society had not the legal power to deal with certain breaches of medical ethics. I beg leave to say that this is an error, as the careful perusal of the Censors' report will show. On the contrary, the Society does possess ample legal powers in this direction, conferred by the Statutes of April 10, 1813, and April 7, 1866.

Respectfully yours,

HENRY G. PIFFARD, M.D.,
Secretary of late Board of Censors.

Obituary.

JAMES AITKEN MEIGS, M.D.,

PHILADELPHIA, PA.

PROFESSOR JAMES AITKEN MEIGS, a physician of marked ability, and an eloquent lecturer, whose knowledge of all subjects appertaining to the philosophy and practice of medicine was as comprehensive as it was profound, died suddenly, on Sunday morning last, November 9th, at his residence, No. 1405 Spruce street, Philadelphia, after a brief illness. A little over one week ago he was attacked with a succession of chills, followed by a fever, which continued for nearly seven days, when, through excessive exhaustion, he was compelled to take to bed. On Saturday evening last, his attending physician, Dr. John H. Brinton, called in the assistance of Dr. Da Costa, one of Dr. Meigs's colleagues in the faculty of Jefferson Medical College, and, after an examination and consultation, Dr. Da Costa pronounced the case one of blood-poisoning. After a severe night of fever, it was found on Sunday morning that he was considerably jaundiced. As the morning wore on, there was, however, an apparent improvement in his condition. He took breakfast with a relish, and after he had lain back in his bed a few minutes, he remarked to his father that he "felt so much improved that he thought he would get up soon and dress." Shortly afterwards his breathing became thick and stertorous, and his father, getting alarmed, hurried from the house for the purpose of summoning Dr. Brinton. On reaching his room, they were shocked to find him dead, life having departed, it is believed, almost immediately after his father had left him. Death was caused by embolism of the heart, which was produced by the blood-poisoning.

Prof. Meigs was born in Philadelphia on the 31st day of July, 1829, of English and Scotch ancestry on his father's side, and Scotch and German through his mother. His primary education was imparted by private tutors. In 1843 he entered the Mount Vernon Grammar School, from which he passed to the

Central High School. Graduating from that institution in February, 1848, he at once began the study of medicine in the offices of Drs. F. G. Smith and J. M. Allen. He matriculated in Jefferson Medical College in October of the same year, and in March, 1851, graduated with high honors. He then began practice in Philadelphia, where he since pursued it until his death. For several years he acted as assistant to the Professor of Physiology in the Pennsylvania College. In September, 1854, he was appointed Professor of Climatology and Physiology at the Franklin Institute, holding the position for eight years. In 1855 he was elected physician to the Department of Diseases of the Chest in the Howard Hospital and Infirmary for Incapables, a place which he held for thirteen years.

In 1857 he accepted the chair of Institutes of Medicine in the Philadelphia College of Medicine, and occupied it until April, 1859, when he was transferred to the Professorship of Institutes in the medical department of the Pennsylvania College, previously held by Professor F. G. Smith, for whom the chair was originally created by the trustees of the parent institution at Gettysburg. While in the latter school in its palmy days he delivered two systematic courses of lectures on physiology, illustrating them with an extensive series of vivisections, which attracted much attention at the time, as no sustained systematic attempt to teach physiology experimentally had been made before in either of the four medical schools then existing in Philadelphia. In June, 1868, on the resignation of the late Prof. Robley Dunglison, he was elected by the Board of Trustees of Jefferson Medical College, Professor of the Institutes of Medicine and Medical Jurisprudence. In August of the same year the Board of Managers of the Pennsylvania Hospital chose him, without the usual canvass, one of the physicians of that institution. These two positions he held until his death.

He was a member of the Philadelphia County Medical Society, of which he was elected Recording Secretary in 1857, and a year later Corresponding Secretary, to which office he was twice re-elected, becoming in 1867 one of the Vice-Presidents, and, in 1871, the President. He was also a member of the Franklin Institute; the Academy of Natural Sciences; the College of Physicians; the State Medical Society of Pennsylvania, and the American Medical Association; in the two latter his membership was permanent. He held a membership in the State Historical Society of Wisconsin; the Biological Department of the Academy of Natural Sciences; the American Association for the Advancement of Science; the Medico-legal Society of New York; the Numismatic and Antiquarian Society of Philadelphia; the New York Lyceum of Natural History; the Linnean Society of the Pennsylvania College at Gettysburg; the Société d'Anthropologie de Paris; the Ethnological and Anthropological Societies of London; the Societas Medicorum Svecarum, of Stockholm; and the International Congress of Prehistoric Archaeology.

He wrote and published many articles of considerable merit, among them one on the physiology of stammering and its treatment by mechanical means. In 1856 he prepared an appendix to the first American edition of Carpenter's work on the microscope. The following year, being chairman of the Standing Committee on Anthropology, he arranged and classified the extensive collection of human crania in the Academy of Natural Sciences, and prepared a systematic catalogue of the collection, which was pub-

lished by the Academy. He also contributed during 1857, to Nott and Gliddon's "Indigenous Races of the Earth," an essay on the cranial characteristics of the races of men, presenting a general survey of human skulls in their ethnical relation; and edited an American edition of Kirke's Manual of Physiology. To the proceedings of the Academy of Natural Sciences, the reports of the Smithsonian Institution, and other like publications, he contributed at various times many original and interesting articles on craniography. He likewise contributed numerous reviews on a great variety of physiological, medical, and scientific subjects to the *Medical Examiner*, the *North American Medico-Chirurgical Review*, and the *American Journal of Medical Sciences*.

He was unmarried, and leaves no relatives alive save his aged father.

JOHN ROBINSON, A.B., M.D., M.R.C.S.

NEW YORK.

JOHN ROBINSON was born in Ireland on the 4th of January, 1809. He was the oldest son of a Methodist minister. By his own exertions he obtained an education, graduating from Trinity College, Dublin, with honor. Immediately afterward he began the study of medicine. He graduated in his profession in 1838, in the city of Dublin, and shortly after visited London, where, on the 27th of July in the same year (1838), he was admitted to membership in the Royal College of Surgeons, England. His diligent attention to his studies while at college, and afterward in the hospitals and dispensaries of Dublin and London, won for him high commendation from his superiors. In 1839 he came to America and settled in this city, and soon enjoyed a large and lucrative practice.

Soon after arriving in New York he formed the acquaintance of the late Dr. John W. Francis, who took him kindly by the hand, and between them there sprang up an intimate friendship, which lasted to the close of Dr. Francis's life. Dr. Robinson once said to the writer, when presenting Dr. Francis: "Here is a man who was my friend when I was sorely in need of one."

In 1845 Dr. Robinson bought an estate (Anna Cora Mowatt's) at Flatbush, Long Island, to which he moved his family in the following year, himself still continuing in the active practice of his profession in New York City during the day, returning to his country home at night.

Dr. Robinson possessed, in a remarkable degree, all the elements of a successful practitioner,—an active mind, quick perception, great personal magnetism, and a remarkable insight of character. He was a hard worker, never shrinking from any demands made upon him in his professional capacity. His was a strong character—proud, independent, positive. To those who knew him but slightly he presented a cold exterior, repelling any approach to familiarity. In his social life, and in the home circle especially, his many virtues shone out with a brilliancy that not even the lapse of time can dim.

He was not a contributor to the medical literature of the day, and his residence out of town prevented his taking an active part in the medical societies. He died at his home in Flatbush, on Friday, Nov. 7th, in the 71st year of his age, of Bright's disease of the kidneys. He married the daughter of a British army officer, who, with nine children, survives him.

ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 9th to November 15th, 1879.

KING, WILLIAM S., Lieut.-Colonel and Surgeon. The extension of his sick leave of absence granted him March 6, 1879, from A. G. O., is further extended six months on account of sickness. S. O. 254, A. G. O., Nov. 8, 1879.

McPABLIN, T. A. and BILLINGS, J. S., Surgeons. Directed to represent the Medical Dep. of the Army at the meeting of the Amer. Pub. Health Association at Nashville, Tenn., Nov. 18, 1879, and upon its conclusion to return to proper station. S. O. 255, C. S., A. G. O.

TREMAINE, W. S., Capt. and Asst. Surgeon. The leave of absence on surgeon's certificate of disability granted him in S. O. 211, Oct. 27, 1879, from headquarters, Dept. of the Missouri, is extended two months on surgeon's certificate of disability. S. O. 255, A. G. O., Nov. 11, 1879.

MEACHAM, FRANK, Capt. and Asst. Surgeon, Ft. Brown, Texas. Granted leave of absence for one month. S. O. 236, Dept. of Texas, Nov. 8, 1879.

CARVALLO, C., Capt. and Asst. Surgeon. To report in person to Col. Albert G. Brackett, 3d Cavalry, commanding troops at Rawlins, W. T., for duty with his command. S. O. 102, Dept. of the Platte, Nov. 10, 1879.

ELBREY, F. W., Capt. and Surgeon. Relieved from duty in Dept. of the South, and to report in person to the Comdg. General, Dept. of the Missouri, for assignment to duty. S. O. 254, C. S., A. G. O.

BYRNE, C. B., Capt. and Asst. Surgeon. When relieved by Asst. Surgeon Comegys, to comply with S. O. 235, C. S., from A. G. O. S. O. 131, C. S., Dept. of Texas.

HAVARD, V., 1st Lieut. and Asst. Surgeon. Granted leave of absence for one month from 25th inst., with permission to apply for one month's extension, provided he furnishes satisfactory medical attendance to the command at Fort Johnston, N. C., at his own expense. S. O. 168, Dept. of the South, Nov. 10, 1879.

COMEGYS, E. T., 1st Lieut. and Asst. Surgeon. Assigned, temporarily, to duty as Post Surgeon at Fort Duncan, Tex. S. O. 231, Dept. of Texas, Nov. 3, 1879.

PORTER, J. Y., 1st Lieut. and Asst. Surgeon. Granted leave of absence for five months. S. O. 254, C. S., A. G. O.

RICHARD, CHARLES, 1st Lieut. and Asst. Surgeon. Relieved from duty at Ft. Buford, D. T., and to report to C. O. Ft. Snelling, Minn., for duty at that post. S. O. 124, Dept. of Dakota, Nov. 2, 1879.

List of changes in the Medical Corps of the Navy, during the week ending November 14, 1879.

GHOS, O. L., Medical Director, and B. T. GIBBS, Medical Inspector, ordered as delegates to represent the medical corps of the navy at a meeting of the National Public Health Association at Nashville, Tenn.

PLEURO-PNEUMONIA.—This disease has recently broken out very extensively in North Staffordshire, England. A number of cattle have been killed, and strong measures are being adopted to stop the infection.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 15, 1879.

Nov. 8, 1879....	0	12	36	1	64	40	1	0
Nov. 15, 1879...	0	15	42	2	84	29	0	0

DR. M. J. DE ROSSET, editor of the *North Carolina Med. Jour.*, has removed to San Antonio, Texas.

"THE WAY IT WAS DONE IN LOUISVILLE."—In our last number, on page 480, a brief article was published with the above heading. Since it appeared, we have seen documentary evidence to prove that the "distinguished New York oculist" had no direct or indirect connection with, or responsibility for, any newspaper or other public notices which appeared concerning him before, during, or after his visit to Louisville.

DIAGNOSIS OF PLEURISY FROM PNEUMONIA.—In the remarks of Dr. Janeway, page 474, it should be stated that there was *not* usually great difficulty in diagnosing pleurisy from pneumonia.

ILLNESS OF DR. KIRKBRIDE.—Thomas S. Kirkbride, M.D., Physician-in-Chief and Superintendent of the Insane Department of the Pennsylvania Hospital, is lying very dangerously ill at his residence on the grounds of the institution in West Philadelphia. The complaint is congestive chills and fever, attended with great nausea and pain in the region of the heart.

THE STAFF OF THE PENNSYLVANIA HOSPITAL.—The name of William Pepper, A.M., M.D., Professor of Clinical Medicine in the Medical Department of the University of Pennsylvania, is very prominently mentioned in connection with the filling of the vacancy in the visiting staff of physicians to the Pennsylvania Hospital, left by the death of Prof. James Aitken Meigs.

THE CHAIR OF PHYSIOLOGY IN JEFFERSON MEDICAL COLLEGE.—The Trustees of Jefferson Medical College, at the suggestion of the faculty, at their meeting on Tuesday evening, November 11th, elected Dr. Henry C. Chapman to fill the chair of physiology during the remainder of the present session, made vacant by the death of Prof. Meigs. The appointment will probably be a permanent one. Dr. Chapman is the son of old Dr. Nathaniel Chapman, who, during the latter part of his life, held the Chair of Physic in the Medical Department of the University of Pennsylvania, and author of a work on "Evolution," and of numerous contributions to the Proceedings of the Philadelphia Academy of Natural Science. For the past year or so he has been demonstrator of physiology in Jefferson College.

THE INTER-STATE MEDICAL SOCIETY met at Mason, Illinois, October 3d; Dr. Lecrone, President; Dr. W. H. Davis, Secretary and Treasurer.

DIPHTHERIA IN BROOKLYN.—There is a prevalence of diphtheria in Brooklyn almost amounting to an epidemic. From sixty to eighty cases are reported each week, with twenty or thirty deaths. This is nearly twice as many as occurred last year at the same time.

MANHATTAN EYE AND EAR HOSPITAL.—The tenth anniversary meeting of the Board of Directors of the Manhattan Eye and Ear Hospital was held on Tuesday, the 11th inst. The Secretary reported that the Hon. E. D. Morgan had recently given to the hospital twenty-five thousand dollars, which would free its building-site on the corner of Forty-first Street and Park Avenue from *debt*, and place the enterprise on a solid pecuniary foundation. The Medical Board, which is by the charter in the governing body of the hospital, reported that four thousand one hundred and sixty-eight (4,168) cases had been treated during the year, and five hundred and sixty-six (566) operations performed, which, added to the work of the previous nine (9) years, made the grand total of thirty thousand and fifty-three (30,053) cases, and four thousand nine hundred and fifteen (4,915) operations.

PAINLESS LABOR.—Dr. A. M. Smith, of Williams-town, writes: "On the 4th I was called to a case of labor. After waiting a while, expecting a pain, I asked: 'Have you any pain?' The answer was, 'No, only a pressure.' I then thought I should have to wait some time, but soon the 'waters' were discharged. I then made an examination, and found the head presenting at the inferior strait; the expulsive efforts regular and strong, *but not a particle of pain*. And within two hours she was delivered, naturally, of twin boys, one weighing seven, the next five and a half pounds, without the slightest suffering from the time I saw her, to the completion of parturition. She had taken nothing in the nature of a narcotic, nor did I give anything. This is my first case, in a practice of thirty years, of delivery without pain."

THE CUBAN YELLOW FEVER COMMISSION.—The Commission of four appointed by the President to visit Cuba and study yellow fever there, has returned to this country and will proceed to prepare a preliminary report, to be presented to Congress in December. During its stay in Cuba the Commission has had the full assistance of the Spanish Government and the co-operation of the best physicians in Havana. It has obtained the medical records and statistics of the hospitals for the past twenty-five years. The Commission is said to have learned many interesting facts in regard to the disease, especially as to its treatment. The most important points will be given to the public in its preliminary report next December.

MRS. MURRAY, wife of Rev. W. H. H. Murray, is a practising physician.

A NEW HOSPITAL is to be built at Woonsocket, R. I., through the liberality of the late Dr. Ezekiel Fowler. The hospital is to be constructed on the pavilion plan and will be practically free.—*Bost. Med. and Surg. Jour.*

DR. SEXTON'S PRIZE ESSAY.—THE MEDICAL RECORD of last week, in alluding to the motto of Dr. Sexton's essay on Affections of the Ear arising from Diseases of the Teeth, through a typographical error made it read Ore Audi, instead of the correct motto, "Ore Auri."

Original Lectures.

TYPHOID FEVER.

A CLINICAL LECTURE DELIVERED AT THE PENNSYLVANIA HOSPITAL, PHILADELPHIA.

By J. M. DA COSTA, M.D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE, AND OF CLINICAL MEDICINE IN JEFFERSON MEDICAL SCHOOL.

TYPHOID FEVER (COMPLICATED BY ORGANIC HEART-DISEASE).

I SHALL first call your attention to-day to two cases of typhoid fever, which are in my wards—one very illustrative of the typical typhoid-fever relapse, and the other presenting some peculiarities which will amply repay a closer study.

The first patient that I bring before you has been sick since the 24th of September—that is as nearly as we can make out. There was diarrhoea at first, and this was soon associated with fever and with a temperature of $104\frac{1}{2}^{\circ}$. On the day of his admission his pulse was not above 88. It is a very remarkable fact that the pulse should remain so low. Looking over the pulse chart from the day of admission, which was probably the fifth day after the inception of the disease, we find the pulse marked down at 86, 80, 60, 66, 70, and so on. During all this time the temperature ran high; that is, it was not what would be a high temperature for fever, but high as compared with the normal. The evening average was about 102° , with a daily morning fall of from one to two degrees. Here at once we strike the fact that the patient's pulse did not correspond with his temperature. Temperature and pulse usually go hand in hand. In this case, on the contrary, there has been a marked disproportion between the fever and the state of the pulse from the very beginning. Did this dissimilarity apply in this case to the frequency of the pulse alone, or to its character also? Only to the former; for the pulse, though slow, was a very compressible one, and in that respect was a typical fever pulse.

I will not say much to you regarding the general symptoms of the case. There was the usual eruption, the spleen was enlarged, and diarrhoea continued moderately active. The temperature to-day is $97\frac{1}{2}^{\circ}$, and it has been as low as that three or four times within the past week. This temperature is lower than the normal; but such a state of affairs is not unusual in convalescence from typhoid fever. His tongue is moist and slightly coated. What about the other viscera? Do they afford us any explanation with regard to the state of the pulse?

Let us make a careful examination. In listening to the heart I can distinguish a most marked systolic murmur, which is harsh, sharp, well defined toward the apex and less marked toward the right base. This systolic murmur is associated with a sharp second sound. There is very evidently something wrong with the heart. It is a nice case for diagnosis.

Are the physical conditions of the heart a result of the fever process, or are they entirely independent of it?

This brings us to a consideration of the state of the heart in fevers. In all low fevers, but preëminently in typhoid fever, there is a cardiac murmur present which is largely due to the condition of the blood, aided, no doubt, by the flabby state of the ventricles. Are we dealing with this kind of cardiac murmur in

this case, or has there been preëxisting and organic disease? The cardiac murmur in this instance does not, I am quite confident, belong to the fever process. In the first place, it was discovered upon the very day of admission—*i. e.*, it was present in the first week of typhoid fever. In the next place, it was and is harsh, rough, and has a most marked second sound associated with it; and, thirdly, it is very strictly limited to the apex. This is not the history, or sequence, of the cardiac murmur of typhoid fever. It comes on late in the course of the disease; it is not rough, and not associated with a distinct second basis sound; and it is not so strictly limited to the apex. It is very plain that the state of the heart has nothing to do with the fever process here.

But the strongest proof which we can derive from the physical signs is that obtained by percussion. The percussion dulness in the cardiac region is very much increased in extent. This proves that the heart itself has increased in size, and I am quite sure that this increase in the size of the heart has not been due to the fever process. This point of diagnosis has a very important bearing upon our prognosis and treatment.

To come back to where we started—what have we now to state regarding the cause of the comparatively low pulse? Is it to be explained by the original mitral difficulty antedating the typhoid fever? I think that it is to a great extent to be so explained. I have frequently found organic heart-disease complicating typhoid fever. In these cases the frequency of the heart's action does not increase in proportion to the height of the fever, but the pulse often remains stationary. I have even known of the coexistence of fatty heart in these cases without any rise in the rapidity of the circulation. This is not an absolute rule, but it is the one which general experience has taught me to follow, *i. e.*, the pulse in such cases is apt to remain stationary, or, at least, not to show any great variation.

This persistence of the normal pulse throughout the typhoid fever process makes me always suspect disease of the heart, and careful examination of the case has generally proven my fears to be but too true.

These points, which we have just been discussing, have a very direct bearing upon the question of prognosis. If the murmur be merely due to the altered state of the blood, we always hope to remove it entirely by means of iron and a general tonic treatment; but this man will recover from the typhoid fever with the cardiac mahady still in force, for the heart-disease in his case antedated the typhoid fever.

Thus you see that we have discovered an accidental, but very interesting condition, which has a very important bearing upon our prognosis and treatment.

RELAPSES IN TYPHOID FEVER.

This case presents a very characteristic typhoid-fever relapse, and will therefore serve us as a very excellent illustration of the true second attack of the disease.

The patient is a German, and, owing to his very imperfect knowledge of English, we have experienced considerable difficulty in obtaining any accurate history from him. What we do know is, that he walked into the hospital on October 3d, in a state of high fever and nervousness, bordering on delirium. He was a very ill man when we first saw him, as was conclusively proven both by his mental condition and by his temperature, which was 104. His pulse upon admission marked one hundred and twenty beats to the minute; his tongue was very tremulous; his ab-

domen was tympanitic, and there were a few rose-colored spots apparent. In addition to these unmistakable signs of the presence of typhoid fever, we were able to distinguish a soft systolic, basic murmur. This last fact would have been enough to prove that the fever must have existed already for some time, had all other reliable signs been wanting. The extent of the blood-changes seemed to indicate that the case had progressed well into the second week when we first saw the patient.

The man remained in the wards, experiencing all the ups and downs usual to the disease. There was some epistaxis, and the fever frequently raised the evening temperature to 103°. The case was treated in the usual manner—mainly by a well-regulated diet. As medicine, five drops of the officinal nitro-muriatic acid, well diluted, were given every three hours, and occasionally a few drops of turpentine were administered, as the state of the tongue and the tympanitis demanded. With this care the case progressed rapidly toward complete recovery, so that on the 18th of October the morning temperature was 99°, and it only rose to 100° in the evening. On the morning of October 20th it was still lower, the record noting 97½°, with an evening exacerbation on that day of only one-half a degree (98°). On October 21st, the morning temperature was again 97½°. The man's mind was clear, the delirium had completely left him, and his appetite had returned to its usual vigor, when suddenly, on the evening of the 21st, the temperature shot up to 101°. Next morning it fell again; but on the next evening it had risen nearly to 102°, and from that time on remained a fever temperature with marked morning remissions and evening exacerbations. Simultaneously there appeared again a typical typhoid-fever rash, which is only now leaving the patient. (You notice that the spots of rash disappear entirely upon pressure, but appear again plainly the moment the pressure is withdrawn.) This state of things has gone on until the second of the present month, since which date the temperature has again been falling, until to-day it has again nearly reached the normal. He now has only one large liquid stool daily.

The resident physician tells me that during the first period of convalescence, that is, during the period between the first attack and the relapse, the stools were almost normal; but the moment the relapse made itself felt, the diarrhoea again appeared in force. The resident thinks that the eruption had at no time entirely disappeared, but that there was certainly a marked increase in its amount when the symptoms of the relapse appeared.

In conclusion, I would merely point out to you that the man is well into his second convalescence; that his tongue is again moist; that his pulse is 76, and his temperature again down to 97½°. This all proves that the second attack also is over.

Those of you who are near enough can see this characteristic ridge on his nails, which is the only remaining sign of the first attack of fever. As regards the cardiac blood-murmur, it still exists, but is very soft, and most distinct over the left base.

The case presents some peculiarities. I do not know that they are so much peculiarities of this relapse as of all relapses, more or less. And, in the first place, you have all, I am sure, noticed the sudden shooting up of the fever process with the inception of the relapse. And then the other curious fact—that the temperature only remained high for a day or so, and then zigzagged with most marked morning remissions and evening exacerbations. You will gen-

erally find this rule to hold good in all relapses. There is a sudden bound up of temperature. It does not attain its height gradually, as in the first attack. It remains high but for a short time, and then the morning and evening changes become most marked. These morning remissions and evening exacerbations are much more marked in the relapse than in the original attack.

I knew that a relapse had taken place the moment my eye caught these zigzag lines on the temperature chart.

As characteristic of the relapse I would also have you notice the immediate reappearance of, or rather increase in the amount of both diarrhoea and eruption. There was also a recurrence of some of the nervous symptoms; not of the delirium, indeed, but of the excessive tremulousness. It is fair for me to guess that the spleen has remained enlarged throughout the course of the disease from the first. It may have gone down in size during the first convalescence, but it certainly swelled up again with the relapse. A very astute clinical observer says that the spleen never decreases in size while the fever process remains; while it may mark the beginning of a relapse by swelling up again, it has never entirely gone down.

A relapse of typhoid fever rarely lasts as long as the first attack. In this case it has been nearly three weeks since the relapse was heralded in, but as a general thing it does not last for more than ten days.

As regards the eruption in a relapse of typhoid fever—until I had made a particular study of this point myself, I did not know that it was the rule for the eruption to appear almost coincidentally with the first symptoms of the relapse. In the original attack, and, indeed, generally, it does not show itself until the seventh or ninth day. The eruption of the first attack and of the relapse does not differ in character. Each relapse of typhoid fever is accompanied by an eruption, and this eruption usually lasts as long as the relapse itself. The eruption is not always in strict proportion to the intensity of the attack—*i. e.*, the intensity of the enteric symptoms. It is generally, however, most marked where the enteric symptoms are most marked.

A relapse in the course of typhoid fever may occur after the patient is to all intents and purposes entirely well of the disease.

There are many other points to which I might call your attention, such as the condition of the nails, tongue, etc., in a relapse, but I must hurry on. The case has been a very typical one.

In the majority of instances of relapse in this disease the prognosis is not bad, the mortality being but very slight if the proper treatment is employed.

The same treatment is employed in a relapse as in the first attack. The patient is put again upon the use of the mineral acids and the turpentine, eight grains of quinia are given daily, and the body is sponged all over every night and morning with cold water. The diarrhoea is limited by opiates and astringents.

What treatment shall we pursue during the rest of the few remaining days of convalescence? The patient has only one movement now a day—we will suspend the turpentine. In place of it I will order the tincture of the chloride of iron in twenty-drop doses, with five drops of muriatic acid, four times daily. I will still keep him upon a liquid diet. He has been taking $f. \text{§} iv.$ of wine regularly every day during the past week; this may be continued. He may have a few stewed oysters, or some milk toast, but no solid food. The quinia will be continued for a few more days.

Original Communications.

THE SPHYGMOGRAPHIC INDICATIONS IN ANEURISM.

By A. T. KEYT, M.D.,

CINCINNATI, OHIO.

(Read before the Cincinnati Academy of Medicine, Nov. 3, 1879.)

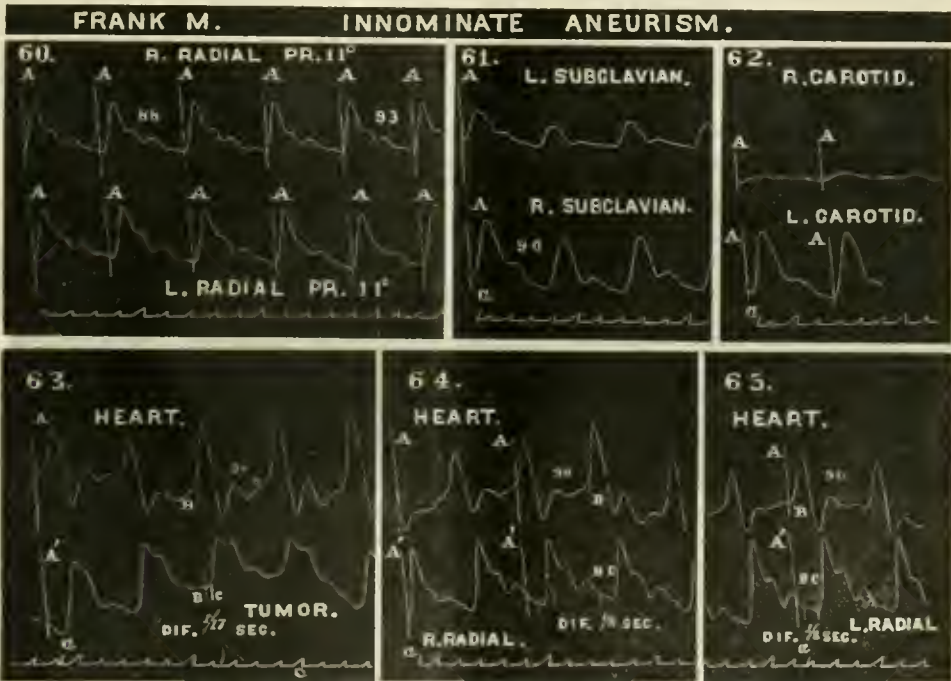

On the authority of a few distinguished names, supported, however, by a comparatively small number of experimental observations, it is currently taught that the pulsations below an aneurism afford two important indications of its presence: first, a characteristic form of pulse—a typical deformation; second, an abnormal delay of the pulse. If these changes exist, the former can be demonstrated with the simple sphygmograph, and the latter with a very perfect differential sphygmograph; and if the question be thus simple and settled, as stated, we have indeed arrived through the graphic method at a wonderful and gratifying precision in the diagnosis of aneurism. The object of this paper is to present some additional facts, and inquire anew as to the real value of these indications.

rim by a tracing with slanting up-stroke, rounded top, and gradual descent without mark of secondary waves.

Dr. Mahomed* gives sphygmographic tracings of several cases of aneurism in which this imperfection is well shown. Of three cases of innominate aneurism verified post-mortem, one shows marked distortion of the right radial as compared with the left, while two present the right radial correct in form and uniform with the left. From his cases, Dr. Mahomed infers that in pure innominate aneurism the right radial pulse presents the "aneurismal trace," while in aneurism of the innominate continuous with dilatation of the aorta, the right radial is little, if any, modified, and right and left correspond.

As regards delay of the pulse below an aneurism, Francois Franck † has contributed important observations. By means of an apparatus devised by himself, he showed, in a case of innominate aneurism, that right radial pulse was delayed on the heart $\frac{1}{100}$, and the left radial $\frac{11}{100}$ second; and in another case the pulsation of the tumor, respectively .21 and .14 second. Thus, Francois Franck esteems delay of the pulse below an aneurism as constant and of the highest diagnostic value.

By means of my apparatus, consisting of two

Explanation of the cuts.—The cuts are exact reproductions from the original glasses, effected by direct photography and skillful cutting. A, A' are lines made by the tracers, respectively, with the glass at rest. B parallel to A cuts the basal point of the proximal trace, and C parallel to A' cuts the basal point of the distal trace. B of the distal trace, also parallel to A', is the same distance from the latter as B is from A of the proximal trace. The space between B and C indicates the time-difference between the pulsations, and its exact value is found by measurement on the corresponding part of the chronogram below. The latter indicates fifths of seconds.

As regards deformation of the pulse below an aneurism, Marey* remarks: "When an aneurism exists on the tract of an artery, one observes below the tumor an important modification of the pulse; the quickness gives place to an extreme slowness, and often the touch is incapable of feeling this pulsation, because of the slowness with which the finger is raised;" and represents the pulse below an aneurism

uniform transmission sphygmographs and a chronogram, all writing on the same glass slide, I have studied the pulsations in three cases of aneurism in which the conditions were verified after death. These cases, with their graphic showings, are here produced:

* La Méthode Graphique, p. 522.

CASE I. *Aneurism of the Innominate.*—For the opportunity of observing this case, I am indebted to Dr. Jos. Ransohoff, who also kindly furnished me the notes of the post-mortem. Frank M—, aged 48 years, presents a prominent tumor at the site of the right sterno-clavicular articulation, which manifests pulsation, thrill, and a systolic murmur. Second sound of the heart clear and greatly intensified. Respiration much embarrassed by pressure of the tumor against the trachea. The graphic records were taken January 1, 1879. A few days subsequently the man died, and the autopsy revealed a large globular aneurism of the innominate artery, about three inches in diameter. The cavity contained fibrous coagula, which encroached upon and obstructed the carotid orifice, but left the subclavian orifice free. The aneurism communicated with the aorta through an opening, only somewhat larger than the normal innominate lumen. The walls of the aneurism were thick and firm, and only showed some degree of thinning and yielding at the apex of the external tumor. The aorta was much dilated from its origin through the entire arch; aortic walls firm. The aortic valves were expanded and thickened, yet competent.

Of the tracings, No. 60 shows the two radial pulses taken simultaneously. It will be observed that the pulsations are well formed—in fact, they show a rather low arterial pressure, but no departure from a normal type; that they are uniform with each other in amplitude, secondary waves, pressure degree and all. Especially will it be noticed that the signal lines (purposely placed near the basal points) are precisely in the same relation to the basal

In the ascending line just after what at first view would be taken as the basil point, is an angle of deviation. Measurement from this latter and the basil point of the heart-trace gives $\frac{1}{7}$ of a second as the time-difference between the pulsations of the heart and tumor—an interval entirely consistent; while measurement from the first point named, and the cardiac basil point would make the heart-tumor interval extremely short—too short, in fact, to be admissible on any just theory as the true representation. Therefore, in this case, the second point is adopted as marking the beginning of the discharge-wave from the heart, which is indeed the true pulse-wave.

The sphygmographic records in the present case demonstrate:

1. That innominate aneurism of large size, communicating with a dilated aorta, may exist without the pulse, beyond, either in form or time, affording any evidence whatever of the presence of such aneurism; witness the correctness and perfect equality in form and time of the two radials.

2. That the effect of such aneurism on the form of the pulse beyond, may be positive and marked; witness the great inequality in form of the two carotids.

3. That the effect of such aneurism on the time of the pulse may be negative as to delay; witness the time between the heart and tumor, between the heart and radials, and the perfect equality in the time registry of the two radials, the two subclavians, and the two carotids.

In this case, also, the demonstration is complete, that the pulse-form was correct in the right radial, because of the free passage to the subclavian, and imperfect in the right carotid because of the ob-

J. B. ANEURISM OF THE ASCENDING AORTA.

points in both tracings, which demonstrates the exact synchronism of the right and left radial pulses. The same characters and conformity of the radial pulses are shown again in Nos. 64 and 65. These representations also demonstrate that the time-difference between the cardiac and radial pulsations is about one-eighth of a second. (A seventh may be attained by extending the measurement beyond the lowest point of the radial traces, which is the more correct method for estimating the interval between the heart and arterial pulses.) Even a seventh of a second would not be greater than the average normal cardio-radial interval, with pulse at 90.

In No. 61, owing to the more superficial position of the right subclavian, its pulse-trace is more ample than that of the left; the pulsations are shown to be synchronous.

In No. 62 the right carotid pulse compared with the left is greatly reduced and deformed, yet there is between the pulses no appreciable asynchronism.

In No. 63 the *ligne d'ensemble* of the tumor-trace undulates in a marked manner with the respiration.

structed passage to this artery. Hence the question arises whether the peculiar pulse-deformation, observed below some aneurisms, does not always depend upon arterial obstruction from filling of the lumen, or pressure of the tumor, or both. The question is one of importance.

The two following cases will aid our investigation. They were in the Cincinnati Hospital, and kindly placed at my disposal for sphygmographic study. The notes were derived from the records and personal observation:

CASE II. *Aneurism of the Ascending Aorta.*—J. Bradford, aged 31 years; suffers from dyspnoea. Presents a prominent pulsating tumor a little to the left of the median line, and two and a half inches above the nipple. The tumor manifests thrill to the touch and murmur to the ear; the latter synchronous with the first sound of the heart, and heard over a considerable area. Tracings taken in August, 1877. Patient afterwards found his way into St. Mary's Hospital, where he died. The autopsy revealed a large aneurismal tumor, involving the ascending aorta

from near the innominate downwards, to near the origin, and extending from the upper border of the second to near the fourth rib; sternum eroded. On section, the walls for the most part were reinforced by thick layers of fibrin; although a number of accessory sacs presented with thin walls, one of which had ruptured into the right pleural cavity and proved the immediate cause of death. The left ventricle was somewhat enlarged and turned posteriorly.

Inscriptions of the heart's apex could not be obtained on account of its recedence from the chest-wall, therefore observations were limited to the tumor and arteries.

No. 66 shows simultaneous tracings of the tumor and right carotid; No. 67 shows the same of the tumor and left radial. The pulse acceleration, 108-113, the diastolism and low pressure will be noticed; also the characteristics of the tumor traces. The deviation in the lower part of the up-stroke, sufficiently indicated in the tumor and carotid traces, but less distinct in the radial, probably marks in this case, as in the first, the beginning of the true pulse-wave, sent from the heart. The preceding lowest point, however, is more definite, and representing, as it unquestionably does, the same stage of the respective pulsations, is more certain and available for measurement. The interval between the pulsations in the tumor and

The aneurism commenced very near the aortic orifice, which latter was considerably dilated, and involved the ascending portion of the vessel, which was expanded into a large flabby sac.

My observations were made January 31st. Nos. 68, 69, and 70 are reproductions of the graphic records. The pulsations of the aneurism were taken at the fourth right interspace, but they were too feeble to produce good traces. However, the basal points are fairly discernible. The heart's pulsations could not be traced.

In the measurements, wherever there might be uncertainty as to the position of the basal points, those were selected which would afford the shortest interval; so if any error of representation exist, it is in making the time differences shorter than the true ones. As shown, the tumor-carotid and tumor-radial intervals, respectively, are closely the same as in the preceding case. The tumor-femoral interval also shows prolongation, and that it is in proper relationship to the tumor-radial interval. The pulse frequency is 127-130, and the pulse-form reflects only a very common type.

Respecting the form of the pulse, these two latter cases support the first in opposing the idea that aneurisms, independent of arterial obstruction, impress upon the pulse beyond a peculiar deformation;

carotid measures, as shown, $\frac{1}{7}$ of a second; and that between the tumor and radial, $\frac{1}{8}$ of a second. If no cause of delay existed the pulse-wave would pass over the distance represented by the tumor and carotid in $\frac{1}{2}$ of a second at the longest, and over the distance represented by the tumor and radial in $\frac{1}{3}$ of a second at the longest. The reason of the apparent greater delay of the carotid pulse compared with the radial is that the retardation takes place in the aneurism, and the pulse-wave reaching the free artery beyond, travels on with its accustomed velocity. In form, both the carotid and radial present the usual features of accelerated, moderately ample, and low-tension pulses.

CASE III. Aneurism of the Ascending Aorta.—Thos. Conley, aged 30 years, has suffered between two and three years from trouble within the chest. Front of chest, especially to left of sternum, bulging, and that on percussion. Pulsation seen and feebly felt over an unusual area, more distinct than elsewhere in the fourth right interspace near the sternum. Absence of thrill, usually no murmur, although a systolic one has at times been detected. Patient very feeble; radial pulse small and frequent; suffers greatly from pain, dyspnoea, and cough. Died suddenly the last of February, 1879. The post-mortem disclosed an extensive aneurism of the ascending aorta which had ruptured and discharged into the right pleural cavity.

the pulse-forms in these cases being only such as often present in other conditions. It seems reasonable, however, that there should be a description of aneurism with free arterial ingress and egress, which would cause the pulse-form of the affected distal artery to differ from that of the opposite unaffected artery, and yet not to the extent of a typical deformation.

In point of delay, these cases accord with François Franck's; and delay of the pulse, as an effect of certain aneurisms, may be accepted as a demonstrated fact. Can we differentiate the aneurisms which produce pulse-delay from those which do not? Case I., in which there was no delay, presented an aneurism of large size, free arterial passages, and *resisting* walls; while Cases II. and III., in which there was delay, presented aneurisms of large size, free arterial passages, and *yielding* walls. The conclusion would follow that the opposite conditions of the aneurismal walls produced the difference observed in the time of the pulses. Observations are needed to determine whether a sacculated aneurism, communicating with the artery by a small opening, would cause delay of the distal pulse. It is conceivable that it would not. From what we have learned of the effect of large aneurisms on pulse-transmission, we are prepared to believe that small ones would cause no appreciable delay.

My own observations indicate that the pulse-retardation in aneurism is much less than that in valvular disease of the heart, and greater than that of any general condition of the vessels and circulation.

Are there any other conditions than aneurism affecting an artery that may produce retardation of its pulse-wave? Two are suspected—namely, arterial

pulse of the obstructed artery notably behind the other in point of time. Nos. 71 and 72 give a fair representation of the results obtained.

The delay of the obstructed pulse compared with the other is about one-thirtieth ($\frac{1}{30}$) of a second, which would about double the usual delay of the radial on the brachial pulse. This demonstration,

obstruction, and the condition recognized as vaso-motor paralysis. These we will examine.

In Case I., cut No. 62, the right carotid pulse, although greatly reduced and deformed by arterial obstruction, shows no appreciable delay. Yet it must be considered, that if delay arise from obstruction, it will be more evident at a distance from the site of obstruction; and that a point of observation so near as in this case, could not be expected to show it, even if initiated. I have tested the effect of tempo-

however, is conclusive only as to the effect of temporary obstruction, and the query remains whether in permanent obstruction in which the artery would be contracted and adapted to the blood-stream, such retardation would occur. Data are wanting for the settlement of this point.

In one of Francois Franck's cases of innominate aneurism, the sphygmographic tracings show the right radial pulse fuller and better developed than the left, and the temperature was elevated 1° F. on

rary compression of an artery on the velocity of its pulse-wave. Two healthy men were separately placed under experiment by first tracing their two radials simultaneously to prove them synchronous; and after compressing one brachial so as to leave the pulse just perceptible, tracing the radials again, and noting the time-relationship of the two pulses. These observations many times repeated showed the

right side. These phenomena were attributed to vaso-motor paralysis, produced by pressure of the tumor on the first thoracic ganglion of the sympathetic. The influence of vaso-motor paralysis on pulse-wave velocity is an interesting question which presents for investigation.

The view has been advanced that the peripheral vascular dilatation and consequent easy flow of blood

in the extremity, due to the vaso-motor paralysis, tend to accelerate the pulse-wave velocity. The view is entirely unsupported, and the specious *prima facie* is disposed of by the consideration that the pulse-wave is distinct from the blood-stream, and that the velocity of the pulse-wave is so much greater than the velocity of the blood-current, that even if variations of the latter exerted their quantum of influence on the former, the effect would be inappreciable.

The opposite view—namely, that the pulse-wave is retarded under the conditions of vaso-motor paralysis, is supported by all the facts brought to light which have any bearing on the question. First, there is the accepted law in physics, that wave-impulses, communicated to a liquid flowing through a tube, are transmitted with a velocity proportioned directly to the rigidity of the tube. Under paralysis of the muscular coat, the artery becomes lax and yielding, and in obedience to the law just stated, would transmit the pulse-wave with diminished speed. Second, the arteries become more rigid with advances of age, and ample observation proves the rule that the velocity of the pulse-wave increases with age. Third, in low-toned arteries, evinced by low-pressure, high-sweep, and dicrotic pulse-traces, it has been observed that the pulse-wave travels slower than in high-toned arteries, evinced by high-pressure, low-sweep, and non-dicrotic pulse-traces; and, especially, in the marked arterial relaxation of adynamic conditions, the pulse-wave velocity has been found reduced. Moreover, as bearing directly upon the question at issue, I am enabled to present the following case and experimental results:

Ernest B—, aged 34 years, fell from a building, striking heavily the back of his neck and head against the ground. He retained his consciousness and power of speech, but suffered paralysis of voluntary motion and sensation of all parts below the neck. The next day imperfect motion, without co-ordination, and imperfect sensation returned to the upper extremities; this apparent improvement, however, was soon lost, and the case again presented the spectacle of complete paralysis of the entire body below the neck. The respiration was labored; heart's action apparently normal; pulse 60 to 80, full and regular; temperature ranging from 102° to 105°F. When the temperature marked 105° the pulse was full and not above 80. The man died on the fifth day after the receipt of the injury. The day before his death, by the kindness of Dr. A. B. Isham, whose patient he was, and to whom I am indebted for the above notes, I was given the opportunity to make sphygmographic observations in the case. The respiration was then very labored, temperature 102½°, pulse averaging 62, full and regular, as shown in the tracings. (See 73, 74, and 75). The tracings, especially the left carotid, are thrown out of horizontal line by the action of the respiration; they are also somewhat defective from extraneous causes; yet the basal points are correctly traced and the successions are truly measured and expressed.

In this case the phenomena of vaso-motor paralysis were fairly declared, and the manifestations of pulse-wave velocity under the conditions are eagerly looked for. The interval between the right carotid and left femoral is .105 second, that between the left femoral and right dorsalis pedis is .125 second; the sum of which intervals gives .23 second as the time-difference of the pulse-wave between the carotid and dorsalis pedis. This is as slow a transmission of the pulse-wave as I have ever observed in unobstructed and non-aneurismal arteries of adults. The young

man L.,* whose pulse-wave velocity was exceptionally slow, gave .0909 second for the carotid-femoral, and .0714 second for the femoral posterior tibial. (See Nos. 18 and 19 here reproduced), the sum being .1623 second for the carotid-posterior tibial interval. So the retardation of the dorsalis pedis pulse on the carotid in the paralytic case was about one-third longer than that of the posterior tibial pulse on the carotid, in the case of L. These facts and considerations would seem to leave little room to doubt that the pulse-wave is retarded in its passage through an artery whose muscular coat is paralyzed.

From this study of the sphygmographic indications in aneurism, the following estimate of their diagnostic value seems fairly justified:

1. *Deformation* of the pulse beyond a suspected aneurism is of little, if any, value as indicating the presence of aneurism, but indicates rather the presence of arterial obstruction which may originate from other conditions, as well as from aneurism. Absence of such deformation is no evidence of absence of aneurism.

2. *Delay* of the pulse beyond a suspected aneurism is strong evidence of the presence of aneurism; and when arterial obstruction and vaso-motor paralysis can be eliminated, the sign is conclusive of aneurism. Absence of such delay is of no value as indicating the absence of aneurism.

3. In aneurism, already diagnosed deformation of the distal pulse indicates the presence of concomitant arterial obstruction.

4. In aneurism, already diagnosed delay of the free distal pulse indicates one with free communications, large cavity, and yielding walls; while absence of pulse-delay indicates one with narrow orifice, or small cavity, or resisting walls.

SUPRA-CONDYLOID AMPUTATION OF THE THIGH.

By M. A. RHOADS, M.D.,

SURGEON TO THE BERKS COUNTY ALMSHOUSE HOSPITAL, AND TO ST. JOSEPH'S HOSPITAL, READING, PA.

In the *MEDICAL RECORD* of April 12, 1879, is published an article on the above subject by Robert F. Weir, M.D., in reference to the general favor with which amputations at the knee-joint are at present regarded. I cordially indorse every word of that article, and herewith present a condensed report of a case operated on a short time ago.

Albert Howe, twenty-three years of age, a laborer, while under the influence of liquor on the night of September 4, 1879, was knocked down and run over by a rapidly-moving railroad train. No less than fifteen heavily loaded freight-cars passed over his right leg, crushing it between the ankle and knee to a perfect jelly. After considerable delay he was brought to St. Joseph's Hospital, exsanguinated, and reacting very slowly. After reaction was sufficiently established, I proceeded to operate, being assisted by two members of the hospital staff. The injury extended diagonally across the leg, from the ankle upward to the front of the knee. On account of the peculiar nature of the injury, it was impossible to adhere to the established rule of a long anterior and a short posterior flap. I thereupon reversed the procedure by making a short anterior and a long posterior flap. After shaping the anterior flap, I divided

* New York Med. Journal, Feb., 1878, p. 134. Cincinnati Clinic, April 13, 1878.

the ligamentum patellæ, disarticulated at the knee, and lastly, shaped the posterior flap, cutting from within outward. I next sawed off the femoral condyles half an inch above their articulating surfaces, and deprived the patella in the same manner of its articulating surface, including both the outer and inner facet. After several ineffectual attempts to bring down the patella, I divided the tendon of the quadriceps extensor, which enabled me to adjust the parts with the greatest facility. The popliteal and a small muscular branch were the only arteries which required the ligature. Common silk ligature was used. The soft parts were then carefully adjusted and the flaps stitched together with silk suture. Proper measures were adopted for the purpose of securing free drainage, and the limb placed in an easy, slightly elevated position. Anodynes and water-dressings constituted the treatment for the first forty-eight hours. At the expiration of that time the soiled dressings were removed, when it was first discovered that a patch of bruised skin was included in the posterior flap, and which showed a disposition to slough. This patch of bruised integument, which was not noticed at the time of the operation (the operation being done at midnight), occupied the central margin of the posterior flap, and covered a surface of about one by two inches. Vigorous poulticing brought about a speedy separation of the slough. While the sloughing was going on, the patient exhibited symptoms of pyæmia, and for about two days it was extremely doubtful if he would recover. But under the use of the tincture of the chloride of iron and quinine, along with stimulants and a liberal diet, faithfully and perseveringly administered, the unfavorable symptoms rapidly disappeared. The wound healed nicely by granulation, making a good solid stump. There is firm and perfect union of patella and femur, and apart from a little tenderness in the line of the cicatrix, the stump is capable of bearing considerable pressure, notwithstanding that it is only a little over two months since the operation. There was no attempt at antiseptic treatment. But there was careful personal attention to every detail in the after-treatment. Perfect rest of mind and body was enjoined. The limb was handled in the most delicate manner. Free drainage was effected, and the parts were kept scrupulously clean.

Reports of Hospitals.

THE PRESTON RETREAT, PHILADELPHIA.

SERVICE OF WILLIAM GOODELL, M.D.

(Reported for THE MEDICAL RECORD.)

LACERATION OF THE PERINEUM.

DR. GOODELL advises the immediate operation, which he has found to be very successful in incomplete lacerations. In complete lacerations it is not as successful as the secondary operation. In the primary operation, in order to put in the stitches accurately, Dr. Goodell recommends that ether be given, and that a sponge be placed high up in the vagina to stop the flow of the lochia, which embarrasses the operator. The stitches are applied as in the secondary operation, and merely twisted together. In the secondary operation, if the sphincter ani is involved, he always embeds the first two stitches. On the eighth day all

the stitches are removed, except the lowest. The feces are then softened by an injection of warm sweet-oil, and the bowels are moved twelve hours later, by an ounce-dose of castor-oil, aided, if necessary, by an injection. After the bowels have been emptied, the remaining stitch is removed.

FUNGOUS VEGETATIONS OF THE ENDOMETRIUM.

In fungous vegetations he removes the unhealthy growth either by the dull or by the sharp curette, or, if the os is sufficiently patulous, by means of a small fenestrated polypus-forceps. The uterine cavity is then cleansed with a saturated tincture of iodine, provided the cervical canal is narrow. But when it gapes, Dr. Goodell prefers Monsel's solution. In the former condition he avoids the use of the iron, because it forms clots which cannot easily be expelled by the womb without giving rise to much pain. He deems the iron, however, the more efficacious treatment of the two.

VAGINITIS.

Non-specific and acute cases of vaginitis he treats by such hot and emollient injections as flaxseed, or slippery-elm bark tea, to which laudanum has been added; the solution which he usually employs contains laudanum $f. \text{ʒ} ij.$ to Oij. of flaxseed. When the inflammation has subsided, vaginal suppositories, containing five grains of iodoform, are ordered twice or thrice daily. In the chronic forms of this complaint, suppositories of tannin, or of iodoform, or long tampons of absorbent cotton, are employed, which have been dipped in astringent solutions of acetate of lead and of zinc to which laudanum has been added.

CONICAL CERVIX.

This condition is treated either by forcible dilatation with a strong uterine dilator, or by lateral section with a hysterotome. If the cervix is sickle-shaped, he performs the section of the posterior lip. The subsequent treatment consists in such local applications as tend to keep the parts from closing up.

PROLAPSE OF BOTH OVARIES

is best managed by the knee-breast posture, and by the administration of such alternatives as tend to lessen the congestion of those organs. Among these he deems the best to be the chloride of ammonium in combination with the bichloride of mercury. Sometimes, however, large doses of the bromide act very happily. He considers this dislocation to be due in a great measure to the congestion of the sexual organs from the use of measures to prevent conception, or from masturbation. He finds that pessaries are rarely useful in this distressing condition. But, if any are employed, he considers Cutter's bulb to be the best. He regards this condition as a very frequently overlooked cause of many pelvic aches and pains, which are attributed very generally to the womb alone.

CLOSURE OF THE VULVA FOR VESICO-VAGINAL FISTULA.

In curable cases of vesico-vaginal fistula in which the urethra has been destroyed, he has twice succeeded in wholly relieving the patient. In one instance this was done by making an artificial recto-vaginal fistula, and in the other by leaving an already existing one intact and closing up the vulva. Whenever practicable he prefers, in this unfortunate condition, when the urethra is unimpaired, to close the vagina as high up as possible, so that the marital relations shall not be interfered with. If the

case be an uncomplicated one, he prefers the use of shot to twisting of the wire, because they form permanent adjusters of the wire and prevent eversion of the edges of the wound.

CARCINOMA OF THE URETHRA.

In timid women who refuse to submit to an operation, he either mummifies the growth with crystallized carbolic acid melted down by heat, or destroys it by applications of chromic acid made with the utmost care, by means of a match whittled down to a point. The excess of acid is afterward neutralized by means of injections of a strong solution of the bicarbonate of sodium. If an operation is permitted, he cuts off the growth with a pair of scissors curved on the flat, and sears the wound with a hot iron wire, or with Paquelin's *thermo-cautère*. He advises the use of an alcohol lamp for heating the wire, because, when an ordinary light is used, the impression upon the operator's retina, made by the bright flame, so obscures his vision that the wire grows cool before he can clearly see the point where the application is to be made. He hastens the healing of the cauterized surface by occasional applications of carbolic acid, or by dusting it with iodoform.

CANCER OF THE CERVIX.

Whenever practicable, the whole cervix is removed by either the hot or the cold wire. If this cannot be done, he removes the malignant growth by scraping or by means of the gouge-forceps, and the surface is subsequently charred with the *thermo-cautery*. This radical treatment is reinforced by subsequent applications of the ethylate of sodium. In these operations upon the cervix Dr. Goodell finds that injections of ordinary vinegar form an excellent means of controlling any embarrassing bleeding. By these means he has succeeded in curing several cases.

CYSTITIS IN THE FEMALE.

Transient cystitis, dependent upon obscure causes, is treated by rectal suppositories containing one grain each of the aqueous extract of opium and of the extract of belladonna. Hysterical cases generally yield to "massage" and electricity. In obstinate cases, Dr. Goodell warmly advocates the dilatation of the urethra throughout its whole extent by the introduction of the forefinger. In the therapeutical treatment of this troublesome disorder atropin is the most efficient remedy, and it may be combined with alkalis or acids, according to the condition of the urine. Injections of a two-grain solution of quinia into the bladder, together with large doses of the same by the mouth, will often improve the condition of the patient. In very bad cases, perhaps the most efficient injection is one of the nitrate of silver, beginning with weak solutions and increasing their strength daily until twenty grains to the ounce solutions are tolerated. These strong solutions should not be allowed to remain in the bladder longer than ten or fifteen seconds. All malpositions of the womb must, of course, be rectified, especially if they have any bearing on the disease.

OVARIOTOMY.

In six cases of ovariectomy performed within the past nine months, with but one death, the following procedure was invariably adopted. A five per cent. solution of carbolic acid was used in the spray, and all instruments and sponges were immersed in a solution of the same strength. The pedicle was treated by the intra-peritoneal method, being transfixed, tied, and dropped within the abdominal cavity. The peri-

toneum was invariably included in the stitches which closed the abdominal wound. All obstinate bleeding points were tied with gut ligature, but the pedicle itself was secured by fine carbolized silk. In three cases where the adhesions were numerous, the glass drainage-tube was employed. The dressing consisted merely of salicylated cotton held in place by adhesive strips, the whole being secured by an elastic flannel binder. Dr. Goodell prefers the above dry application to Professor Lister's wet dressing. The after-treatment consisted in opium enough to allay pain, and in one tablespoonful of milk combined with lime-water given every three hours for the first forty-eight hours. As soon as flatulence escaped from the bowel the supply of food was increased. The patients were prepared for the operation by a soap-bath on the previous evening, and by the administration of one grain of opium at bedtime. On the following morning one grain of opium and ten grains of quinia were given. Dr. Goodell always operated at eleven o'clock in the morning, as being the time when the vital forces are at their best. When high temperature ensued, it was reduced by the application of an ice-cap, which was found to be an efficient means of lowering bodily heat.

PURPERAL FEVER

is invariably treated by intra-uterine injections of a warm two per cent. solution of carbolic acid. Ten-grain doses of quinia are given every four hours until marked cinchonism is produced. Morphia is administered in doses sufficiently large and as frequently as necessary to relieve pain. The whole surface of the abdomen is painted with the compound tincture of iodine, and covered with a large mush-poultice. If it is deemed necessary to open the bowels, large doses of calomel are used.

SOBE NIPPLES.

Chapped nipples are treated either by the glycerole of the nitrate of lead in a solution containing from twenty grains to one drachm to the ounce, or by a mixture of two drachms of iodoform to the ounce of balsam of Peru. The balsam is used because it disguises the smell of the iodoform.

GATHERED BREASTS.

When an abscess forms in the mammary glands, an early incision is practised. If the pus lies deep or is lodged behind the gland, a cutaneous incision is first made, a grooved director is then pushed into the abscess, and the opening is enlarged by the uterine dilator. The breast is then tightly strapped with adhesive plaster, and treated by a dry compress of oakum. Should the abscess show symptoms of becoming chronic, its walls are overdistended by an injection of a three per cent. solution of carbolic acid. This overstretching is practised so that the acid may reach every nook and cranny of the purulent cavity.

THE TREATMENT OF THE FUNIS.

As soon as the child cries lustily the cord is cut, and the umbilical portion being firmly held by the thumb and forefinger, the free end is "stripped" of Wharton's jelly and of any blood that may remain in it. Any blisters of Wharton's jelly which still remain are emptied by this process of "stripping," are nicked, and their contents squeezed out. After the removal of the pressure of the thumb and forefinger all bleeding usually ceases, and then the cord is tied. No subsequent dressing is thereafter used, for the cord rapidly dries without smell and drops off without leaving a sore behind.

VAGINISMUS.

Dr. Goodell has never yet been compelled to resort to the deep, posterior incision of Dr. Sims, although in two cases he was obliged to snip off irritable *carunculae myrtiformes*. He treats this disease precisely as he would treat an anal fissure. If the local spasm does not yield to constitutional treatment and to vaginal suppositories of morphia, belladonna, carbolic acid, and iodoform, he puts the woman under ether, and forcibly stretches the vulvo-vaginal opening either by means of the two thumbs, or by the fore and middle fingers of each hand.

NOTES ON CONGENITAL SYPHILIS.

Congenital syphilis appears either before or after birth. The labor is usually premature, and the first symptom of the disease is the hoarse cry to which the child gives utterance. The bullæ soon show themselves. The disease in utero takes the form of placentitis, the exudation presses the blood out of the small capillaries, and so gradually starves the product of conception; or there may be a gummy tumor or fatty degeneration of the placenta, so causing premature labor. In some cases the labor is precipitated by atheroma of the cord.

He explains the hoarse cry, above referred to, by the presence of syphilitic ulcers on the mucous membrane of the child's throat and air-tubes. Such children are always puny and sickly-looking. The bullæ appear in the course of a few hours after birth, and are first visible on either the scrotum, hands, or feet.

If the disease is not already in existence at birth, it usually begins some time between the second week and third month after birth. The child cries a great deal at night. This cry, which is occasioned by the incipient bone-disease, is muffled and hoarse. Another symptom is the snuffles: the child's nose is all stopped up, and then a scalding coryza comes on. Then the child grows wizened and thin, and its skin lies in rolls and wrinkles. The so-called *copper macule* appear, or the complexion gradually assumes a coffee-and-milk hue. Then the eruption comes out all over the body and stamps the case indisputably as one of syphilis.

FISSURE OF THE RECTUM.

Dr. Goodell treats fissures in two ways, viz.: Ist, by cutting through the adjacent muscular fibres; and 2d, by overstretching the sphincter ani muscle. He much prefers the second method. To do this he inserts his two thumbs into the rectum, and pulls them apart until the sphincter begins to yield or he feels the rami of the ischia on each side. To do this requires the exercise of considerable force.

HEMATOMA OF DOUGLAS'S POUCH.

The patient is kept absolutely quiet, and astringent drinks, such as sulphuric acid, lemonade, etc., administered. Opium enough is given to lull the pain and keep the patient thoroughly quiet. For a number of hours following the attack but very little food is given. Stimulants are avoided. Occasionally the vagina is packed with ice.

HABITUAL CONSTIPATION.

The following prescription is a very favorite one with Dr. Goodell:

R. Ext. colocynth. comp. gr. ij.
Pulv. rhei. gr. j.
Ext. belladonna gr. ʒ.
Ext. hyoseyani gr. ss.

M. divide in pil. No. 1.

S. To be taken at bedtime.

In some cases $\frac{1}{16}$ of a grain of strychnia is added with profit to the foregoing. In most cases "massage" is employed with the very best results.

PERIMETRITIS.

Dr. Goodell has the patient put to bed, and kept quiet. Flying blisters are then applied locally over the abdomen. A series of these blisters are used. Together with this local treatment, $\frac{1}{4}$ of a grain of the bichloride of mercury, with ten grains of the muriate of ammonia, is given thrice daily in the mist. glycyrrhizæ comp.

The following mixture is also often used:

R. Hydrarg. chlo. corros. gr. j.
Liq. chlo. arsenitis. f ʒ ss.
Mist. ferri chlo.,
Acid. muriat. dil. āā f ʒ ij.
Syrupi f ʒ ij.
Aque. q. s. ad f ʒ vj.

M.

S. One tablespoonful after each meal.

THE DIAGNOSIS OF OVARIAN CYST.

Dr. Goodell distinguishes ovarian cyst from dropsy in the following manner: In a case of ascites the abdomen, when the patient is placed on her back, is flat on top, and bulges out at the sides. In ovarian cyst the very opposite is true. In ascites the intestines float up to the top, and resonance is elicited upon percussion. In ovarian cyst percussion gives only flatness.

There is one certain way of settling the question of the existence or non-existence of ovarian cysts, and that is by means of the aspirator. The fluid of ascites is straw-colored and limpid; that of a monocyst is perfectly clear and limpid, like spring-water; that of a polycyst is thick, dark, and turbid, from disintegrated red blood-corpuscles; that of an oligocyst is usually of a milk-and-water or of a light brown color. The discovery of the Drysdale ovarian cells in an aspirated fluid is proof positive of its origin.

MISCELLANEA.

Dr. Goodell frequently employs the following: (1) A modification of Basham's mixture.

R. Tinc. ferri chlor. f ʒ ij.
Acid. acet. dil. f ʒ ss.
Liq. ammon. acet. f ʒ ijss.
Caracoe,
Syrup. āā f ʒ j.
Aque. q. s. ad f ʒ viij.

M. S. One tablespoonful after meals.

And:

R. Tinct. ferri chlor. f ʒ ij.
Acid. phos. dil. f ʒ ij.
Spts. limonis. f ʒ j.
Syrupi f ʒ ijss.
Aque. q. s. ad f ʒ vj.

M. S. A tablespoonful after each meal.

WOMEN AS DRUGGISTS.—At the last meeting of the Council of the London Pharmaceutical Society, two ladies, who had previously passed examinations as pharmaceutical chemists, were elected members of the Pharmaceutical Society with but one dissenting vote. The question of the admission of women had for some years been discussed before this Society, but was always voted upon unfavorably.

Progress of Medical Science.

METALLO-THERAPY IN HYSTERIA.—REPORTED CURE OF A CASE BY ZINC.—The following instance is worthy of note as bearing upon a question which is now exciting discussion among neurologists. Dr. Moricourt reports a case of hysteria in a girl eleven years of age, in which, after the failure of other methods of treatment, he had recourse to metallotherapy with the most satisfactory results. Copper, gold, and tin were applied successively without appreciable result; but zinc produced, in a few minutes, sensations of titillation and heat under and around the metal, followed by a notable augmentation of sensibility and muscular power. The oxide of zinc was then prescribed internally, two pills containing three-fourths of a grain each being given daily, and in a few days the convulsive attacks disappeared. They returned again two weeks later, after the treatment had been discontinued for four days, but disappeared once more as soon as the use of the pills was resumed. A month later the patient began to suffer from gastralgia; the dose of zinc was doubled, and frictions to the epigastrium with zinc ointment were ordered, and in a few days the gastralgia was cured. Shortly after this the patient received a severe fright, which was followed by contraction of the limbs and loss of the power to walk. The use of the pills was continued, and the daily application of zinc armatures to the legs and thighs ordered. The contracture yielded readily, and in a week the patient was able to walk a long distance, but she began again to have hysterical attacks and gastralgia. Investigation showed that the armatures used had been, by mistake, made of four metals—copper, iron, zinc, and tin; plain zinc bands were substituted for them and the patient had no more hysterical attacks. The gastralgia, however, yielded more slowly. The armatures produced sensations of pricking and burning, and left red marks which were visible for twenty-four hours. Treatment was continued for about six months, when the cure seemed to be permanent. The parents suspended the treatment several times, contrary to orders, because they thought the child was cured, but were compelled to resume it again in a few days by a return of the symptoms.—*Gazette des Hôpitaux*, Sept. 9, 1879.

ON FATTY EMBOLISM AFTER INJURIES OF THE BONES.—M. Déjérine reports the results of a series of experiments on dogs, undertaken with a view to determine what injuries of bones are followed by fatty embolism of the lungs. His results differ from those of Flourenoy and Hahn, as he did not succeed in producing fatty embolism, either by fractures of the skull, or by simple fractures of the extremities. The result sought for was only obtained in cases in which he irritated the bony marrow by the introduction of foreign bodies into the medullary cavity, and it varied very greatly in degree according to the nature of the foreign body employed. In one set of cases he used pieces of iron wire, which, acting simply as inert foreign bodies, excited only a moderate degree of inflammation, and the fatty embolism was so slight that it would have been entirely overlooked, if the lungs had not been subjected to careful microscopical examination. In other cases tents of laminaria were substituted for the iron wire, and the difference in the effects produced was most striking, the fatty embolism of the lungs being as marked as in several cases

in men, in which it had been the principal, if not the sole cause of death. The fat-drops were present in abundance in the veins of the extremity operated on, and filled the capillaries of the lungs to such an extent, that those organs were almost entirely injected with fat. Dr. Déjérine was led to use laminaria by the comparative failure of the iron-wire experiments, and by the theory advanced by Chassaingnac to account for the presence of oil-globules in the pus of osteomyelitis, viz.: that the bony marrow, when increased in volume by inflammation and compressed against the bony walls of the cavity, enters the vessels and appears on the surface of the bone. The laminaria swells after its introduction, compresses the marrow, and the same result is obtained as in inflammation. The conclusion drawn by Dr. Déjérine from his experiments is, that fatty embolism of the lungs does not follow indifferently all experimental injuries of bones, but that for its production it is necessary to place the animals under conditions similar to those following severe injuries of the bones in men.—*Gazette Médicale de Paris*, Sept. 13, 1879.

PREPARATION AND USES OF THE ALBUMINATE OF IRON.—Prof. Donitz, of Tokio, speaks in the strongest terms of the value of the albuminate of iron in anæmic affections, which, in Japan, form an unusually large proportion of the maladies that come under the charge of a physician. He prepares it in the following way: the whites of one or two eggs are stirred briskly in 150 c.c. of water, and a solution of six drops of the liq. ferri. perchlor. to 30 c.c. of water is added very slowly, the mixture being constantly stirred. When the first drops of iron are added, a cloudiness appears, which, however, has mostly disappeared by the time all the iron has been added; the addition of a few drops of very dilute muriatic acid accelerates the clearing up of the mixture, but with proper care it is superfluous. Any large flakes of albumen which remain after the mixture of the two solutions, can be filtered off with comparative ease, as the albuminous fluid passes more readily through the filter after the addition of the iron. Water is then added to the filtered fluid until its volume is brought up to 150 c.c., when a tablespoonful of it will contain exactly half a drop of the liquor ferri. perchlor. When muriatic acid is used, great care is necessary, as a very slight excess is liable to cause the mixture to become cloudy at a subsequent period. This iron-albuminate can be dried and preserved in the form of powder, and when needed for use it is simply redissolved in water. During the last two years, Prof. Donitz has employed this preparation in a very large number of cases of anæmic affections, and has been thoroughly satisfied with the effects produced by it. He has found that it can be tolerated without difficulty by the weakest stomachs, even when no other preparations of iron can be borne. Most of the cases in which he employed it were examples of simple anæmia due to badly prepared and insufficient food, but he has also found it particularly serviceable in the terrible disease called in Japan "kakke," and known in India under the name "beriberi." In this disease, which is still but imperfectly understood, the blood becomes very watery, and, in fact, the hydræmia constitutes the first tangible, pathological alteration. At first, Prof. Donitz administered the albuminate of iron internally in cases of this affection, but the results were not entirely satisfactory, as it proved useful only in mild cases and in convalescents; finally, however, he tried it hypodermically, and, thus employed, he found it all that could be desired. In

some cases, in which for the sake of experiment no other treatment was used, the daily excretion of urine increased in about a week from 150 c.c. to 900, and even 1,400 c.c. the œdema and serous transudations rapidly disappearing at the same time. The ordinary dose for hypodermic use in mild cases was four Pravaz syringefuls daily (about one drachm); these were usually injected in two different spots at the same time. In severe cases the dose was doubled, the above quantity being injected twice a day. An induration sometimes remained for several days at the point of injection, but no abscesses ever formed. Prof. Donitz tried a stronger preparation than the above, but soon gave it up, as he found it very much more difficult to prepare, while it did not seem to produce any better effects. A marked increase in the excretion of urine, which is one of the first signs of improvement in kakke, was usually observed on the third day after this treatment was begun. When used internally, the ordinary dose was a tablespoonful three times a day.—*Berliner klin. Wochen.*, Sept. 8, 1879.

MYXŒDEMA.—At a recent meeting of the Clinical Society of London, nine cases of this curious disease were reported by various observers. It was first described, some years ago, by Sir William Gull (see *MEDICAL RECORD*, Sept. 20, 1879), as a "cretinoid condition supervening on women in adult life," and subsequently by Dr. Ord, who called it myxœdema. Its chief pathological characteristic is a universal mucoid degeneration of the connective tissue of the body.

Upon post-mortem the body is found swollen; the various organs are not much affected. The microscope shows everywhere a great increase of connective tissue; the fibrillar element is more abundant, while the interstitial mucus-yielding element is still more increased in amount. The connective tissue looks like the sheath of the umbilical cord. These changes are best seen in the skin, glandular organs, and coats of the arteries. Their encroachment on other tissues and organs seems to be the cause of death.

The affection seems to be confined to married women between the ages of 30 and 50. No hereditary influence or special exciting cause has been given.

The symptoms are characteristic and the disease can be easily differentiated. The patient generally begins to swell and increase in size, the face has a puffy, anæmic look like that of Bright's disease, but there is no œdema, and rarely any albumen in the urine.

The movements become slow, the mind grows lethargic, and the perception dull; at times the patient has delusions, or becomes of sullen temper; the appetite is lessened, the bowels are often constipated.

The temperature is very low, toward the close of the disease falling to 92°, 90°, 88° F., and in one case even to 77° just before death. The course of the disease is chronic; it generally lasts ten or twelve years; but the patient gradually becomes more stupid and lethargic, and, though there may be an interval of improvement, death seems to be inevitable.

No satisfactory treatment has been discovered; iron and cod-liver oil have so far been oftenest given.—*Medical Press and Circ.*, Oct. 15, 1879.

SUBCUTANEOUS OSTEOATOMY.—The subject of subcutaneous osteotomy, which has excited increased attention during the past five or six years (see *MEDICAL RECORD*, Nov. 22d), was brought up before the surgi-

cal section at the last meeting of the British Medical Association, and elicited a number of valuable papers from prominent surgeons. The discussion was confined chiefly to the operation for genu valgum and ankylosis of the hip, for the cure of which affections it has been most often employed.

Subcutaneous osteotomy was first performed by Langenbeck in 1848, but it was soon adopted and extended by American surgeons. The operation was placed on a more definite basis by Mr. Wm. Adams, of London, who, in a series of cases, sawed through the neck of the femur within the capsule, and obtained excellent results. It soon appeared, however, that the procedure was only applicable in those cases, generally of rheumatic or pyæmic origin, where the head of the bone preserved its integrity. As a complement to the Adams operation, therefore, Mr. Gant devised that of dividing the shaft of the femur below the trochanters. The operations of both Mr. Adams and Mr. Gant were done by making an incision with a narrow knife, and then withdrawing the knife and passing a saw along the track thus made.

In 1876, Dr. Ogston, of Edinburgh, applied the operation to the correction of genu valgum. Operating antiseptically, he pierced the knee-joint, split up the femur, and then detached the internal condyle. This operation, which has often been repeated by others, has now become an established success, and is reckoned among the triumphs of modern surgery. It has been greatly modified, however, and the question of the best way to operate subcutaneously for genu valgum is still unsettled. Thus, Mr. Lister makes a free incision over the internal condyle, and then makes a section or partial section of the lower end of the femur with a chisel and without entering the joint. This plan is essentially the one devised by Professor Macewen, of Glasgow, except that the latter makes a small incision, and only a partial section; the bone then is broken in straightening the limb.

Mr. B. E. Brodhurst does not believe that osteotomy is often called for in genu valgum, and denies that the internal condyle in this affection is often lengthened. His favorite plan is to divide the external lateral ligament and the biceps tendon.

Mr. Richard Barwell, who believes that in genu valgum there is curvature of the upper end of the tibia, as well as of the lower end of the femur, first partially divides, and then fractures the latter. In a few weeks he does the same thing to the tibia. He generally uses the Lister spray.

It appears from the papers presented that the following questions regarding subcutaneous osteotomy for genu valgum are not yet fully settled: 1. Which is the best plan? 2. What is the best instrument? 3. Whether the Lister spray be necessary? 4. At what age should the operation be performed? 5. In what cases will subcutaneous section of the tendons and ligaments be sufficient?

The facts given show: 1. That the operation is usually successful, whatever the method. 2. That incision into the knee-joint is not necessary for the success of the operation. 3. Authorities are against the practice of cutting the external condyle instead of the internal, and also against the necessity of cutting the fibula, as is sometimes done. 4. The chisel is the instrument generally used.

DR. MAYNSELL, a prominent Dublin physician and medical writer, recently died at the age of seventy-four years.

THE EXPERT TESTIMONY IN THE HAYDEN TRIAL.

The trial of the Rev. Mr. Hayden for the murder of Mary Stannard has become a notable one in every respect. The circumstances surrounding the crime were mysterious, and no direct evidence in regard to the murderer could be obtained. The State, however, has spared no efforts or expense to throw light upon the matter, and for this purpose they have secured a great deal of expert testimony. Through such agency some entirely new contributions to forensic medicine have been obtained, as well as valuable testimony upon other allied matters.

To appreciate what has thus been done the facts in the case may be briefly recited. Somewhat over a year ago a young woman, named Mary Stannard, was found dead by the side of the road in Madison, Conn. One side of her throat was deeply cut, and there was a bruise on her head. The post-mortem examination discovered ninety grains of arsenic in her stomach, which viscera showed also signs of inflammation from the presence of the poison. A small cyst, about the size of a hickory-nut, was found growing in one of the ovaries.

From various suspicious circumstances the Rev. Mr. Hayden was arrested on the charge of having committed the murder. The girl had worked as a servant in his family at one time, and he was alleged to have had improper relations with her. The result, as claimed, was that she thought herself pregnant, that the accused shared in the belief, and hence the crime. The presence of the ovarian cyst, it was testified, might have caused symptoms of pregnancy.

It was also learned that about the time of the murder Mr. Hayden had bought some arsenic of the village druggist, and a package of arsenic was found in Hayden's barn. The defense asserted that this was the arsenic bought by Hayden, and that it had been intended for rats.

On the shirt which Hayden wore on the day of the murder, experts asserted there was a spot of blood. In the thumb-notch of the knife, and on a stone which lay near the place of the murder, a few more corpuscles were claimed to have been found.

The three points upon which the expert testimony chiefly bore were: the significance of the ovarian tumor; the distinguishing of the arsenic in the barn from that in the village drug store, and the identification of the blood-stains.

The question of the arsenic excited by far the most attention, and it was here that novel and original work was done. To discover the presence of arsenic is sufficiently easy, but here, in addition, it was attempted to trace each specimen of the mineral to the particular drug store where it was bought. Thus, if it could be proved that the arsenic which was found in the barn, and which Hayden claimed to have bought at a certain druggist's, was unlike that on hand at that druggist's, while the arsenic in Mary Stannard's stomach did resemble it, a very important evidence for the State would be established. The prosecution brought three experts who testified that the "barn" arsenic was unlike the druggist's arsenic, or at least unlike that of the wholesale dealer of whom the druggist purchased. It was testified, also, that the "stomach" arsenic was much like that in the drug shop. It was well established by these experts that specimens of arsenic varied according to the particular method of manufacture, and that packages from different sources could, as a rule, be distinguished. The points relied on for this are: the proportion of crystals to dust and broken fragments, the size of the crystals, the size of the broken fragments, and the scratching, or its absence, on the face of the crystals. In ordinary commercial white arsenic the proportion of crystals is about one-half. Of the specimens examined at the trial, the "barn" arsenic differed from the druggist's arsenic in the size and proportion of crystals as well as in the character of the fragments.

The evidence, on the whole, was pretty conclusive as to this point, that differences do exist in different specimens of arsenic, and that these differences will make it possible sometimes to trace the article to its original source. At the same time it is to be remembered that arsenic, having different microscopical appearances, may be sent out from the same manufactory; also that a mixture of the various samples of the drug is liable to occur in every retail druggist's establishment. These facts, established by the defense, will probably make it rare for this kind of evidence to carry great weight. Ordinary juries will hesitate to hang a man because the proportion of arsenical crystals is only one-fifth.

The testimony in regard to the blood-stains has also considerable interest. At the preliminary trial, a year ago, an expert testified that the stain on a cer-

tain stone was made by blood. At the later trial he admitted this to be a mistake, and said that the supposed stain was due to the presence of a low order of plant, whose spores resemble blood-corpuscles. Another expert testified that there were about fifteen blood-corpuscles on Hayden's knife, and that a small stain on the prisoner's shirt was also due to blood. The tests for blood, and the possibility of distinguishing human blood from that of other animals, were very freely discussed, the scientific expositions being occasionally varied by touches of personal animosity toward rival experts.

It is not more than two years ago that a high English authority, Dr. Francis Ogston, asserted that there was no single test for blood which was absolutely certain—referring, of course, to the detection of small amounts of dried blood. We are impressed with the march of science, therefore, when learned experts swear that fifteen blood-corpuscles have been found in the notch of a knife, and, further, that these are from human blood. Such assertions were made at the trial, and were based chiefly upon the microscope and the micrometer. We are not disposed to deny their validity. Within the last five years the study, particularly of the measurement of the blood-corpuscles, has received much attention, and there are undoubtedly a few persons who can, in most cases, distinguish human blood from that of other animals.

The testimony of the experts at the trial has, on the whole, been creditable to them. No scientific facts asserted by them have been impeached, although their application to the present case may have been weakened. The trial will be found to show, however, some of the weak points in our expert system. Thus, the prosecution sent out Dr. Dana for the purpose of learning facts which would enable it to prove a difference between the "barn" and the "stomach" arsenic. He found some such facts, and can scarcely be expected to be entirely free from bias or enthusiasm in applying them. The prosecution has also got its experts to testify on the other side. The expert testimony is not and can never be perfectly impartial under such arrangements.

The trial has been conducted with so much care and ability that we can have confidence that, whatever the verdict, it will be a just one; and, in any event, it has brought to light scientific facts which will undoubtedly be of help toward securing the ends of justice in the future, and will perhaps deter people a little from using arsenic, at least, to gratify their criminal impulses.

A RUSSIAN REMEDY FOR DIPHtheria.

The Minister of Russia to the United States has recently written a letter to the *New York Herald*, recommending to the American public the benzoate of soda for the treatment of diphtheria. This drug, he states, has been used with great success by a number

of prominent Russian and German physicians, among whom are Professor Klebs, of Prague; Dr. Senator, of Cassel; Dr. Braham Braun, and Dr. Letzerich. The latter treated twenty-seven cases, eight of them being very malignant, with this medicine, and all recovered except one.

The remedy is given internally every two or three hours, and is also applied externally and used as a gargle.

It is rather strange that with so admirable a specific as this is claimed to be, the Russian government has been obliged to appoint a commission to investigate the epidemics of diphtheria which are ravaging the country with increased violence.

Similar remedies to the one suggested have already been used in diphtheria, and good results obtained; but nothing has ever received such universal endorsement as iron, chlorate of potash, and alcohol; nor is it likely that the eminent diplomatist's suggestion will produce any great change in the therapeutics of the disease. There have been dozens of drugs for which equally good results have been claimed; and, doubtless, Mr. Shishkin would have spoken more cautiously, or not at all, if he had made himself a little familiar with the history of specifics for diphtheria. His letter recommending benzoate of soda was doubtless written in a spirit of great benevolence; and, nevertheless, there is no particular good—indeed, there may be harm—in exciting hopes among the laity that a specific has been found. The doctor is expected at once to know about it and to cure his cases with it. It should be remembered, too, that medical journals exist wherever medicine exists, and that there is a constant interchange of views. No reliable discovery in medicine remains long without being published throughout the whole medical world.

The moral of this is, that Mr. Shishkin had better tend to his diplomacy, and let the doctors take care of diphtheria.

HOSPITAL SUNDAY.

Some time ago we advocated the plan of selecting a particular Sunday, and devoting all the contributions on that day to the hospitals. It was also advised that this should be supplemented by a hospital Saturday, so that all creeds and hospitals might receive the expected benefits. We are glad to announce that this plan has now been adopted. On the last Sunday of the year, and the Saturday preceding, collections will be made among churches, and also among individuals, for our local hospitals. The plan is comprehensive, and will not allow even those who prefer to stay at home, and praise the Lord at the domestic hearth, to escape the opportunity of charitable giving. Donors are to be allowed to signify which particular institution they wish their money to benefit. Those contributions which are left undesig-

nated will be placed in the hands of a committee, who will distribute them as their judgment dictates. The committee is composed this year of the Mayor, the President of the Chamber of Commerce, Postmaster James, Drs. Dix and Hall, and Messrs. H. E. Pellew, Cornelius Vanderbilt, and Robert Waller.

With the guaranty of such names, the success of the hospital Sunday plan is assured. It has for a long time been a popular and efficient method of raising money in London, and thus has the endorsement of past experience. Nearly all of our hospitals depend more or less upon charity, and concerted effort in their behalf will furnish to them much more relief. It will, in addition, attract the attention of the public to these institutions, and make their work and their wants more generally known. This is a consideration which alone will have much weight with those who wish well of the enterprise.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

It will be seen from our report of the recent meeting of this Association that the subject of yellow fever and of quarantine occupied their attention almost exclusively. The question of the exotic character of the disease was discussed at length. There is still, probably, a majority who believe in its always being imported; but the majority is smaller than it was last year, and the tide seems to be turning to the other side. There were no contributions to the clinical history or pathology of the disease. The value of quarantine was almost unanimously endorsed. The plan of adopting absolute non-intercourse found no defenders this year. Quarantine also was not claimed to be more than a useful auxiliary. The value of disinfectants during epidemics was not shown to be very great. In regard to prophylaxis, a general confidence was expressed in strict sanitary cleanliness to prevent the return of an epidemic. It was further claimed that if a case is notified early, the disease can, by prompt measures, be prevented from spreading.

We shall have occasion to comment upon the work of the Association more fully at another time.

NITRITE OF AMYL AS AN ANTIDOTE FOR CHLORAL.—The nitrite of amyl was recommended as an antidote for chloral by Dr. Coghill some time ago. A case illustrating its value for this purpose has been reported by Dr. Jas. McCullough, in the *Canada Lancet*. He was called to see an old lady one night, and found her pale, insensible, and almost pulseless. She had been taking chloral regularly as prescribed to her by a physician; but had, by accident or otherwise, taken an extremely large dose. Five drops of amyl were given her by inhalation; in a few minutes the extreme pallor gave place to a healthy glow, the respiration became deep, and the pulse fuller. She did not, however, regain consciousness, and in two hours became weak again. The amyl was repeated with the same beneficial results. After this, with the help of brandy, she completely recovered.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 22, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

THE PATHOLOGY OF YELLOW FEVER.

IN accordance with a previous promise to the Society, Dr. E. C. SEGUIN exhibited a number of slides prepared by Dr. H. D. Schmidt, of New Orleans, illustrating the pathology of yellow fever. After referring to Dr. Schmidt's paper in a recent number of the *New York Medical Journal*, he stated that the gentleman had performed thirty complete autopsies of patients dying of yellow fever, and had found that the chief characteristic of the disease was an hyperæmic condition of all the internal organs, notably those of the central nervous system. In connection with this hyperæmia was noticed an effusion of blood-pigment along the course of the blood-vessels. Another important lesion was a fatty degeneration of the essential elements of the various organs. In the brain, for instance, there was an unnatural amount of granular matter. The latter condition was quite difficult to make out in the specimens exhibited, but Dr. Seguin had no doubt that it was present in a marked degree in the fresh specimens as examined by Dr. Schmidt. The same changes were noted in the tissue elements of the liver, spleen, kidney, and in several sections of the sympathetic. Dr. Seguin stated that Dr. Schmidt had examined the living subjects, with great care, and with a view of discovering bacteria, but in every instance the results were negative.

DR. T. E. SATTERTHWAITE then presented a number of microscopic slides prepared by Drs. W. H. Porter and A. M. Jacobus, illustrating the lesions in the case of yellow fever, which was described at the meeting of October 8th.

The following is the result of the post-mortem examination by Dr. W. H. Porter, the history of the case having been previously published:

Pericardium and heart.—The pericardium was normal and contained about half an ounce of clear straw-colored fluid. The heart-substance was soft, flabby, and slightly fatty. Valves free and normal; weight, ten ounces. The cavities of the heart contained fluid blood of a dusky-brown color, without coagula.

Pleura and lungs.—Both lungs are pretty firmly attached to the chest-wall over a great part of their extent by adhesions of long standing; this condition was most marked on the right side. On section, both lungs were found congested and œdematous, but they exhibited no evidences of recent or old phthisis.

Spleen.—Soft and flabby; weight six ounces.

Kidneys.—Soft, congested, and yellowish-red in color. Weight of right, five ounces; of left, five and one-half ounces. Capsule normal in thickness and not adherent. Cortical markings a little wavy. In the pelves of the kidneys numerous bright red ecchymotic spots (such as are sometimes seen in acute scarlatinal nephritis).

On microscopic examination, the epithelium throughout the kidney was swollen and intensely granular. The tubes contained numerous small granular casts of a yellowish color. At the apices of the pyramids, the collecting tubes were nearly stripped of epithelium. The epithelium that remained was

intensely swollen, and even more granular than in other parts of the kidney. At several points the tubes, and in some cases the blood-vessels were blocked with numerous little bright bodies of a uniform size, arranged in a regular manner at equal distances from one another. They looked at first like spherical bacteria, but on close examination with high powers (immersions 1-10, W. Wales, and No. 12 Prazmowski), the bodies proved to be mostly, if not wholly, rod-bacteria of the usual kind. They took a deep purple color, with hematoxylin.

The interstitial tissue was unusually well-marked, but it was difficult to say whether the change was due to the imbibition of fluid or to a new growth of connective tissue.

Bladder.—The bladder was absolutely empty and gave no indications of inflammation, except near the urethral orifice.

Vagina, Uterus, and Ovaries.—Upon laying open the vagina, it was found to contain a dark, dirty-looking fluid resembling decomposing blood; on extending the incision into the uterine cavity more of this dirty fluid blood was met with; also quite a large mass of clotted blood and mucus occupied the body of the uterus. The ovaries appeared to be normal. The right contained a corpus luteum of menstruation, only a few days old—it was said that she commenced to menstruate two days before death.

Stomach and Alimentary Tract.—The stomach contained a considerable quantity of light-colored fluid, probably in large part the milk and brandy taken before death. The whole surface was slightly congested and overlaid with a soft coating of mucus, which, when brushed off, showed many little minute black points representing black vomit matter; these little black points seemed to be at the mouths of the follicles. On microscopic examination all the coats of the stomach appeared a little thickened, but most markedly the mucous or follicular coat. Some of the little points were seen under the microscope. The epithelia of the mucous and peptic glands were thought to be abnormally granular. At the mouth of the follicles the epithelium was frequently wanting, and in them was seen in places lymphoid corpuscles. There was neither congestion of the stomach, nor extravasation of blood. The connective tissue seemed increased in amount.

Liver.—The vessels in the transverse fissure were free; the gall-bladder was not distended. The liver tissue was of a deep yellow color and had a fatty look. It was also deeply jaundiced, evidently the "yellow liver" of "yellow jacket." Weight 100 ozs. On microscopic section, the liver was found to be in an advanced stage of fatty degeneration. The fat-globules were abundant about the central vessel, but were also quite numerous throughout the whole extent of an acinus, and seemed to have been developed at the expense of the liver-cells, so that the cell was converted into a fat-globule, presenting an appearance that is seen in the so-called fatty infiltration. The other liver-cells were more granular than normal, and it was with difficulty that any nuclei could be recognized. There was also a marked increase in the connective tissue of the organ, and in places the separate cells were surrounded by new-formed connective tissue, as has been observed in syphilitic cirrhosis. At several points in the sections collections of bright little bodies of uniform size were seen, arranged in a regular manner, just as in the kidney. They were bacteria, and seemed to be in the blood-vessels.

The brain and spinal cord were removed, but exhibited no lesions to the naked eye. Unfortunately,

the fluid in which they were placed failed to preserve them.

It was stated by Dr. Satterthwaite that the presence of bacteria in the specimens could be explained in various ways, and he did not believe that it in any way sustained the notion that these organisms produced the disease. Accumulations of bacteria of similar appearance he had found in persons suffering from other diseases not contagious or infectious.

DR. AMIDON referred to a case of yellow fever which occurred at the New York Hospital in 1877. The patient came from Fernandez, and twenty-four hours after admission was seized with black vomit, dying soon after. The liver, stomach, spleen, and kidneys were the only organs examined microscopically; in each of them, except the stomach, the tissue-changes were similar to those described by Drs. Seguin and Satterthwaite. No changes were found in the gastric-mucous membrane, notwithstanding black vomit had existed. There were no evidences of hemorrhages, no particular congestion of the vessels, and no change in the gastric epithelium. In the kidneys very many of the tubuli were clogged with desquamated epithelium and pigmented granules. In the liver there was present fatty degeneration of the periphery of the acini.

REMOVAL OF GANGRENOUS LUNG.

DR. LANGE presented a portion of the gangrenous lung of a woman, aged forty years, who, shortly after her confinement, was attacked with empyema, accompanied with a temperature of 104°, and the expectoration of gangrenous material. Dr. L. saw the case in consultation, and performed thoracentesis in the ninth intercostal space. About a quart and a half of fluid was evacuated, after which a mass presented itself into the wound and was accordingly removed. This proved to be a portion of the gangrenous lung. At the time of reporting the case the woman was still in a very critical condition.

SYSTO-SARCOMA OF TESTICLE.

DR. LENTE presented a sarcoma of the testicle, which he removed by operation from a lad aged twenty years, and a resident of Newburg. The growth first showed itself about a year ago, and gradually increased, until it measured seventeen inches in circumference. A portion of the scrotum, which contained an abscess, was removed with the tumor. The patient made a good recovery. The tumor was composed of fibrinous and cartilaginous masses, and presented a very characteristic appearance of sarcoma.

DR. KEYES referred to two similar cases in which he had operated several years ago, and in which the disease had reappeared in the retro-peritoneal glands.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 6, 1879.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

THE Academy was called to order at 8 P.M., and the minutes of the last stated meeting were read by the Secretary, DR. H. T. HANKS.

The Librarian, DR. LAURENCE JOHNSON, reported that since the last stated meeting 509 bound volumes, 158 unbound volumes, 442 pamphlets and medical journals, 11 maps, and 3 *fac-simile* letters had been donated to the library. The bound volumes included

those presented by Dr. Abram Dubois, and those donated at the last stated meeting by Dr. Purple.

The Corresponding Secretary, DR. JOHN G. ADAMS, made a report in which brief reference was made to the late George W. Callender, F.R.C.S., F.R.S., and

THE DEPARTMENT FOR DISEASES OF CHILDREN IN MT. SINAI HOSPITAL.

The paper for the evening was read by DR. A. JACOB, and consisted in a report, with epirical remarks and specimens, of a series of interesting cases which had been under his observation in the department for diseases of children in the Mt. Sinai Hospital as permanent physician in the service. The service was originated in March, 1879, and although since the organization the number of patients had not been large, yet a fair proportion of the cases had been highly interesting. After giving the number of cases of general febrile diseases, diseases of the respiratory organs, diseases of digestive organs, of the nervous system, chronic diseases, such as syphilis and rachitis, diseases of the skin, and neoplasms, etc., he reported in detail several cases, the more important of which were the following:

Matilda W—, *æt.* 8 years; admitted March 30th. *Unilateral inflammation of the tonsils.* A rare affection, unless the result of local irritation. Usually not purely inflammatory, but infectious in character.

Victoria B—, *æt.* 12 years; admitted March 18th. *Admitis; otitis media; enlarged spleen; chronic pneumonia; gastric catarrh; cardiac disorders; suppurating adenitis.* As a rule, diseases of childhood are simple and uncomplicated, and, for that reason, a correct diagnosis can be made with greater facility than in adults. In this respect the case was exceptional, and presented a number of complications which, as a rule, are seen only in adults.

Philip B—, *æt.* 10 years; admitted March 12th. *Endocarditis, articular rheumatism, and chorea minor* occurred simultaneously. The usual order is articular rheumatism, then rheumatic endocarditis, and after some time, chorea minor. In the rheumatism of infancy and childhood there are many cases in which diagnosis of endocarditis is made because of a murmur, and yet that murmur will disappear, sometimes, when the severity of the other symptoms subsides.

Typhoid fever. Most of the severe cases presented the characteristics of the average typhoid fever of infancy and childhood; the symptoms were irregular in character, and not very marked. In the case of Louis S—, *æt.* 9 years, and admitted June 24th, the anatomical conditions were exactly the same as we would expect to find in the adult. The general rule, however, holds good that subjective symptoms and some objective, particularly the high temperature, are not what one would be led to expect from consulting books alone. [See MEDICAL RECORD, vol. xvi., Nos. 17 and 18.]

Dr. Jacobi presented a specimen in which there were marked ulcerations and perforation in the intestine, and yet the patient did not have any diarrhoea.

Thomas C—, *æt.* 3 years and 9 months. *Intra-cranial tumor.*

Lena H—, *æt.* 8 years; admitted March 10th. *Typhlitis; repeated attacks of peritonitis; recovery.* The child was discharged in July.

Mary C—, *æt.* 3 years; admitted May 28th. *Multiple congenital hyponata.* The tumors were situated in the lumbar region, the gluteal region, and the scapular region. That in the lumbar region was upon both sides of the spinal column, more to the left than to the right, and was five inches by four inches; the

one in the scapular region was the smaller of the remaining two, and was two or three inches in diameter. An operation was performed for the removal of the largest tumor. The case, however, without fever, but with progressive emaciation and increasing hyperæmia, lingered until July 2d, and then terminated fatally.

Fannie C—, *æt.* 3 years; admitted September 4th. *Typhoid fever complicated by catulepsy.* In the course of the typhoid fever, whooping-cough developed. On the 23d of September it was hoped she was on the way to recovery, without further complication. On that day, however, the first slight spasm of the eyelids was noticed which preceded the development of well-marked catulepsy. On the 15th of October the child was convalescent.

Flora McD—, *æt.* 3 years; admitted March 6th. *Chronic inflammation of the knee-joint; free incision into the cavity and scraping out the granulations; operation and dressings done under Lister; carbolic acid and thymol; plaster-of-Paris splint; healing of the wound nearly complete, July 2d.*

At the close of Dr. Jacobi's report the PRESIDENT remarked as follows: The duty which those connected with hospitals and public institutions owe to the profession at large is one which, I think we must all agree, is very much neglected by many who hold these public appointments. Such positions, in connection with our hospitals, give large opportunities for observation and accumulation of experience which those in private practice do not have; consequently they are acquiring knowledge which should belong, in propriety, to the profession. While these appointments involve extra labor and care, they bear with them extra rewards, and the duties are of a kind the rewards of which all should acknowledge.

Another reason why the profession should have opportunity to become more familiar with hospital practice by the aid of reports, such as that to which we have listened this evening is, that there is an immense amount of medical knowledge which, from the very force and nature of the circumstances, cannot appear in medical works. Much can be done to fill this missing page by those who are brought into personal contact with hospital practice, as illustrated by the labors of Chareot, Troussseau, Louis, Graves, Stokes, and many others, who acquired a vast deal of knowledge with regard to methods of physical diagnosis, with regard to modes of operating and skill in the application of therapeutics, which has never been transmitted through the writings of such men, and which never could be transmitted, and which were only known either through personal contact, or through tradition.

It is the province of such an association as this to supply that want; and it is its province to bring out all that kind of knowledge, as far as it is possible to do so, which is not otherwise set forth in systematic treatises and medical works.

I will ask the Academy to pardon me for making one more remark, and that is, that diseases of children occupy a large part of the time of general practitioners, and they constitute a class of affections which are of very great importance. I might point out a great many reasons why they deserve much more special study and care and attention than they now receive.

In the first place, the seed of hereditary disease is first developed in childhood, and here, if ever, are such diseases to be met successfully, and, if possible, obliterated; for in after-life it is too late, as a rule, to deal with them for their eradication.

In the second place, the development of those diseases is simple in character, unmodified by previous habits, by former disease, or by former treatment; consequently, they constitute a class which possesses more than usual interest.

It is, therefore, with great pleasure and pride that I feel we have been the means of bringing out the information we have received this evening. I had made preparations to have a full debate at this time, but my impression is that the paper should be first printed, and then carefully studied, and when that is done, the cases and the highly scientific remarks upon them may give rise to a valuable and interesting discussion, and one which will do the Academy great credit.

On motion, the discussion was postponed until an evening should be assigned by the President.

The President then announced the reception, through Dr. Ellsworth Eliot, of \$25 from a friend of the Academy, to be expended in the purchase of books, and the Academy then adjourned.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Seventh Annual Meeting at Nashville, Tennessee, November 18-21, 1879.

(Special Report for THE MEDICAL RECORD.)

FIRST DAY—WEDNESDAY, NOVEMBER 18TH.

The American Public Health Association met at 12.30 P.M., in the Hall of the House of Representatives. About two hundred members were present. President J. L. Cabell, M.D., in the chair.

A NATIONAL MEDICAL LIBRARY.

After an opening prayer, and an announcement of the names of the members present, the committee appointed a year ago to memorialize Congress in regard to the publication of the index catalogue of the National Medical Library, made its report. Dr. R. W. Mitchell, its Chairman, stated that, at the last meeting of Congress, \$20,000 had been appropriated for printing and binding the first two volumes of this work. As the complete work would embrace ten or twelve volumes, however, it was necessary that further appropriations be made, and it was advised that the committee be continued.

In connection with the report, Dr. J. S. Billings stated that the Army Medical Library was now the largest exclusively medical library in the world, embracing 50,000 volumes, and as many pamphlets.

At the close of the report, a number of invitations from private and public citizens of Nashville were announced and acknowledged. It was voted that, in subsequent discussions, each member should be limited to ten minutes. Dr. E. M. Hunt, as Chairman of the Publication Committee, stated that the volume of the proceedings of the last annual meeting would soon be published.

COL. GEORGE E. WARING, of Newport, R. I., then read a paper on

THE DRAINAGE AND SEWERAGE OF CITIES.

Col. Waring referred to the expense and imperfections attending the present sewer system. As a remedy he proposed the following plan: There should be two systems of drainage in every city; one for carry-

ing off the storm-water, the other to remove the excreta, etc., from the houses and other buildings. The storm-water should be carried off by superficial drains that can be easily cleaned. Even surface-drainage of storm-water might do. The sewers for house-drainage should have a minimum diameter of six inches, and they should not exceed that size until they had accumulated a sufficient flow, at the time of greatest use, to fill them half full. The upper end of each branch sewer should have a Field's tank for flushing it at regular periods. The house connections should be without traps, and there should be a continuous pipe leading to the roof of the house. By such arrangements there would be no such thing as sewer-gas.

In the discussion that followed, the plans suggested by Col. Waring were in the main endorsed.

Dr. A. AMES said that Col. Waring had not sufficiently brought out the question of the final disposal of the sewage matter.

Dr. E. M. HUNT thought that the fulness of a sewer was not the thing to be depended on in determining its proper size. This should be regulated also by the velocity of the current, and the hydraulic pressure.

EVENING SESSION.

At the evening session Governor Marks, Dr. E. M. Wight, President of the Tennessee Medical Society, and Mayor Thos. Kercheval delivered short addresses of welcome.

Dr. CABELL then delivered the

PRESIDENT'S ANNUAL ADDRESS.

This was very long, and consisted of an elaborate historical review of the organization of the National Health Board, with a defence of its course and work. Some facts concerning the work of the Havana Yellow Fever Commission were given. It was found that yellow fever had been endemic in Havana since 1761, and that it was thought to have been imported at that time from Vera Cruz. The sanitary condition of the Cuban sea-port towns, the commission said, is wretched, the death-rate amounting sometimes to forty or fifty per thousand. The pathological part of the commission's work is yet unfinished. Dr. Sternberg has, however, discovered one characteristic pathological change, viz.: a fatty degeneration of the white blood-corpuscles. He was unsuccessful in inoculating any lower animals with yellow fever, and had been unable to isolate any *contagium vivum*.

President Cabell gave a full history of the Gamgee refrigerating ship. He discussed the subject of international quarantine regulations, and also of international quarantine.

He cited the following propositions as having been established by last summer's experience:

1. That in yellow fever unrestricted family intercourse is one of the most fruitful means of spreading the infection.
2. That when prompt notice is given of a case imported into a previously uninfected locality, proper measures energetically employed will generally suffice to arrest the disease.
3. That even in case of an epidemic it is possible, at least in the smaller places, by very rigorous efforts, to stamp out the disease.
4. That a properly directed quarantine may be an effectual security to sea-ports and inland towns against the introduction of contagious diseases; and that the policy of absolute non-intercourse is unnecessary.

SECOND DAY—NOV. 19TH.

At the opening of the morning session 36 new members were elected. The Association accepted an invitation to a reception by Mrs. James K. Polk.

DR. CHAS. F. FOLSOM read a paper by Elliott C. Clark, C.E., on

CITY SCAVENGERING IN BOSTON.

Scavengering includes removal of house-effects, ashes, house-dirt, offal; also the cleaning of streets, privy-vaults, cesspools, etc. Such garbage, in Boston, is all removed in properly constructed wagons. It is taken to the department depot and dumped on platform cars. These take the garbage out of the city, where it is sold to the farmers. The sales last year amounted to \$28,000; the cost of collecting to \$76,000. One hundred and eighty-five miles of streets are cleaned every week, some of the streets being swept every day. The work on the whole is very satisfactorily done.

Dr. H. M. THOMSON, of New Orleans, read a paper on the

DISPOSAL OF GARBAGE AT NEW ORLEANS.

There are three ways, he said, in which garbage may be disposed of. It may be cremated, or dumped, or transported from the city. In New Orleans the dumping system had long been employed, and with very bad results. In considering the question of reform, cremation was thought too expensive. They adopted, therefore, the plan of having all the garbage put on scows, towed down the river two miles, and then dumped into the current. This plan had worked admirably.

The discussion that followed the above papers was shared in by a large number of members. There was considerable testimony to the difficulties of making a profitable disposal to farmers of garbage and house-effects.

Dr. E. H. JAMES, Secretary of the Association, read a lengthy paper by Dr. E. G. Janeway, of New York, on

MUNICIPAL SANITATION.

Much of the space was devoted to the subject of tenement-houses and their proper construction. The recent law passed in New York concerning this matter was dwelt upon very favorably. Dr. Janeway's paper also discussed the subject of contagious diseases. In regard to their sporadic origin he did not consider the matter settled, and recommended the question to country doctors, as being best situated to obtain facts bearing on the matter. The writer did not think that the refuse from slaughter-houses was calculated to develop scarlet fever. He did not believe yellow fever to be contagious. The paper concluded with proposing a series of resolutions containing suggestions to health boards for securing more uniform and accurate vital statistics.

AFTERNOON SESSION.

Dr. A. L. GIBSON, U.S.N., read a paper upon the subject of

THE PROTECTION OF THE INNOCENT AND HELPLESS FROM VENEREAL DISEASE.

The paper was excellently written, though somewhat rhetorical for a scientific contribution, and was incomplete in the matter of facts. It advocated the establishment of some form of regulation of prostitution. It was listened to with much attention. At

its close several members expressed their approval of its sentiments.

It was voted that a committee of five be appointed to consider the subject of the address and report to the Association. Drs. A. L. Gibson, W. B. Griffith, J. McKeller, Sternberg, and P. H. Baillache were appointed.

EVENING SESSION.

The evening was devoted chiefly to discussing the question of the

EXOTIC ORIGIN OF YELLOW FEVER.

Dr. A. A. WOODHULL, U.S.A., in an elaborate paper, claimed that in the epidemic at Savannah, in 1876, the yellow fever did undoubtedly originate at Savannah. Frost, Dr. Woodhull believed, might extinguish an epidemic, but would not necessarily de-vitalize the fever cause.

Dr. T. J. TYNER read a paper on

THE ETIOLOGY OF YELLOW FEVER IN MEMPHIS.

He claimed that it arose there as well as in other American cities *de novo*; or, admitting it to be exotic, he was sure its spread was absolutely dependent on local conditions.

A number of members shared in the subsequent discussion. They were about equally divided on the subject on the exotic character of the disease. Drs. Early, Hargis, and Wise were believers in the indigenous theory; Drs. Campbell, Austin, and Elliott were against it. Dr. Elliott contradicted the conclusions of Dr. Woodhull in regard to the Savannah epidemic.

THIRD DAY—NOV. 20TH.

Twenty-four members were elected at the opening of the morning session.

The following officers were then chosen for the ensuing year: *President*, Dr. John S. Billings, U.S.A.; *First Vice-President*, Dr. Choppin; *Second Vice-President*, Dr. R. C. Kedzie; *Treasurer*, Dr. J. B. Lindsley, of Nashville, Tennessee.

It was voted to hold the next annual meeting at New Orleans.

During the balloting for officers, a paper was read by Dr. W. H. BREWER, President of the Connecticut Board of Health, on the subject of

ROTTEN WOOD.

Dr. BREWER related experiments which he had made, showing that wood of any kind, when left in still water, will produce low putrefactive changes. The water dissolves out the nitrogenous constituents of the wood, and these decompose. In running water various fungi become attached to the wood.

Dr. J. D. PLUNKET, President of the Tennessee Board of Health, read a paper on

COTTON AS A FOMITE.

A history was given of the evidence upon the question, and it was concluded that cotton was, from its porous and flocculent nature, particularly adapted to become a carrier of infectious disease. Notwithstanding this, it was a remarkable fact that no case of yellow fever has been recorded as having originated from contact with cotton. Whether this were accidental, or due to germicide virtues in the cotton-ool, could not be determined. Meanwhile, however, cotton should be treated as dangerous.

A paper upon

THE LATE MEMPHIS EPIDEMIC

was read by Dr. G. B. THORNTON, President of the Memphis Board of Health.

He stated that the prevailing opinion among Memphis physicians was, that the yellow fever was not imported into Memphis. Dr. Thornton thought himself that the balance of facts was on that side. In regard to the alleged filthiness of the city, he said that though not in the condition it should have been in the beginning of the summer, it was quite as clean as many other cities, and that the lack of perfect sanitary arrangements was largely unavoidable. At present he considers the city as clean as any in the country. He did not think that, when yellow fever was firmly established, either disinfection or isolation could eradicate it.

He thought, however, that by thorough disinfection and proper local sanitation during the winter, the disease could be driven away.

At the conclusion of the paper, the following

EXECUTIVE COMMITTEE

was elected: Dr. C. B. White, New Orleans; Dr. J. L. Cabell, Virginia; Dr. E. M. Hunt, New Jersey; Dr. J. D. Plunket, Tennessee; Dr. C. F. Folsom, Massachusetts; Dr. A. L. Gihon, U.S.N.

EVENING SESSION.

The session opened with a paper on

THE YELLOW FEVER QUARANTINE OF THE FUTURE,

by Dr. H. F. Campbell, of Augusta, Ga.

Dr. CAMPBELL argued for a strict quarantine during epidemics, on vessels, railroad-trains, etc. Never, he said, let the latter come nearer than twenty miles to the infected spot without changing cars; carefully disinfect the baggage, etc., but let the individual pass, even if the fever is upon him.

At the conclusion of the paper, Dr. Holliday, of New Orleans, said that at present all New Orleans physicians were agreed upon the value and necessity of a quarantine that did not imply absolute non-intercourse. In regard to the exotic character of the disease there were still differences; many thought that the disease had now become endemic.

Dr. J. H. RANCH reported a case seeming to show that cotton had carried the yellow fever contagium.

Dr. A. N. BELL made a strong appeal to the Association to extend every possible aid to Memphis.

JUDGE J. W. CLAPP said he thought that they should all be humiliated that the Association, after three days' discussion, was no nearer any satisfactory conclusions than before. Judge Clapp defended Memphis from the charges of neglect and filth which had been made against it.

Dr. BAILEY did not believe in quarantine for yellow fever, nor in the exotic character of the disease.

Dr. PETERS, of New York, thought that the conveyance of yellow fever was more like that of typhoid fever than anything else.

FOURTH DAY—NOVEMBER 21ST.

At the Morning Session 150 new members were admitted. The following papers were read: "Quarantine in Arkansas in 1879," by R. G. Jennings, of Little Rock; "Camps and Depopulation at Memphis, 1879," by John F. Cameron, and "Yellow Fever in New Orleans," by S. S. Herron. Dr. Holliday, of New Orleans, read the report of the Committee on Subjects Submitted by the American Association, recommending a national quarantine of vessels to

prevent the importation of the first case of yellow fever; the establishment of quarantine hospitals; the Governments, national, State, and municipal, to make provision for the removal of unacclimated persons; the exclusion of upholstered furniture, rugs, and carpets from railroad cars during epidemics. The report further shows the important results which have sprung from the incorporation of the National Board. President Cabell announced the appointment of the following Advisory Council: Alabama, R. D. Webb; California, Henry Gibbons; Florida, S. C. Cobb, of Pensacola; Georgia, H. F. Campbell; Illinois, J. H. Ranch; Indiana, J. F. Hibberd; Mississippi, Wirt Johnston; Louisiana, D. C. Holliday; Maryland, James A. Stewart; Massachusetts, Azel Ames; Pennsylvania, Henry Hartshorn; Ohio, T. C. Minor; Missouri, Dr. Homan; Rhode Island, E. M. Snow; Tennessee, J. W. Clapp, of Memphis; Virginia, L. L. Joyner; Michigan, H. B. Baker; West Virginia, James E. Reeves; District of Columbia, Dr. Toner; New York, Dr. Harris; North Carolina, F. F. Wood; South Carolina, H. Leiby; Connecticut, C. W. Clumberlain; New Hampshire, L. F. Conn; Vermont, H. D. Holtar; Texas, Dr. Rutherford; Wisconsin, E. L. Griffin; Minnesota, W. Hunt; New Jersey, L. Lilly; Arkansas, A. L. Breysacher; Kentucky, Pinckney C. Thompson; Delaware, Dr. Bush; United States Army, Dr. McParlin; United States Navy, B. F. Gibbs; National Board of Health, Stephen Smith; Commissioner of Education, Gen. John Eaton.

President Plunkett, of the Sanitary Council of the Mississippi Valley, has appointed the following committee to arrange plans of operations between all the State Boards of Health in the Union: Dr. Hewett, Dr. Pinckney Thompson, of Kentucky; Dr. Griffin, of Wisconsin; Dr. T. A. Atchison, of Tennessee; Dr. Choppin, of New Orleans; and Dr. Rice, of Mississippi.

EVENING SESSION.

At the night session, resolutions were adopted to the effect that the present National Board of Health has been of such service to the country that it is not expedient to make any change in its organization; that the investigations by the board are approved, and should be continued to the prevention of other diseases as well as yellow fever; that Congress should appropriate sufficient funds to enable the board to secure talent and apparatus; that no change in the existing quarantine law should be made without careful consideration; that it is expedient for the National Board to call an International Congress for the discussion of quarantine; that it is clearly the duty of the Government to establish a quarantine station at the mouth of the Mississippi River. The Association then adjourned to meet in New Orleans next November.

THE NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, Nov. 3, 1879.

Dr. J. C. SHAW, PRESIDENT, IN THE CHAIR.

The Society was called to order at 8.20 P.M., and the minutes of the previous meeting were read by the Secretary, Dr. W. J. MORTON.

MISCELLANEOUS BUSINESS.

Dr. SPITZKA presented the resignation of Dr. J. C. Davis, which was accepted.

Dr. E. C. SEGUIN moved a reconsideration of the resolution presented by Dr. Hammond, at the last stated meeting, regarding the Consulting Board to the Insane Asylum in the Department of Public Charities and Correction.

The motion was seconded by Dr. L. C. GRAY, and adopted by the Society.

On motion by Dr. SEGUIN, the Secretary was instructed to correspond with the Commissioners of Charities and Correction, and respectfully request information regarding the functions of the Consulting Board.

SUBACUTE MYELITIS.

THE PRESIDENT then exhibited microscopical sections from the spinal cord of a case of subacute myelitis that had the following history:

A female patient, *et.* 50, he saw in consultation May 26, 1879. The supposed cause of her illness was catching cold several months previously. Her temperature was 98½ F., and pulse, 100. She suffered from pain and soreness in the muscles, and about the chest from a sense of tightness. There was some wasting of the muscles of the extremities; loss of faradic reaction; neither vesical nor rectal disorder. At the end of two weeks her general condition was about the same, but was unable to speak; although conscious, yet was not aphasic. The case terminated fatally soon afterwards, without special changes in the clinical history. At autopsy nothing abnormal and relating to the nervous system could be seen with the naked eye. The spinal cord was properly hardened, and, on examining microscopical sections, the cervical and lumbar regions were found to be the seat of lesion, which consisted in atrophy, pigmentary and fatty degeneration of the ganglion cells, and in some of them vacuoles could be seen. The medulla had not yet been examined.

A CONTRIBUTION TO THE PATHOLOGY OF ACUTE CENTRAL MYELITIS, BY DRs. E. C. SEGUIN AND E. K. HENSCHEL.

Dr. E. C. SEGUIN reported the case, which had a history briefly as follows: A male patient, *et.* 33, unmarried, originally of good constitution, infected with syphilis, not conscious of straining his back or of catching cold, at 4.30 p.m., Oct. 8th, was taken with pain in the lumbar region, located over the kidneys. Soon after he made ineffectual efforts to micturate. At 9.30 p.m. he made ineffectual efforts to empty his bladder, and was not able to sleep. At 11.30 p.m. he had great desire to micturate, and when he arose from his bed he found that he was unable to stand. There was tingling in his toes and feet, and marked anesthesia. The sensation at the knees was apparently perfect. He was restless, and his anxiety was great during the after-part of the night. Pulse, 120; temperature, 100 F.

Oct. 9th, 3 p.m.—Anesthesia had extended upward to the level of the umbilicus; paralysis complete below. Catheter was used. An enema of soap and water was retained. At 8 p.m. he suffered from much pain in the sides of abdomen, lower part of thorax, and epigastrium. No symptoms referable to the hands or arms. Lower extremities absolutely paralyzed and anesthetic. Spine only slightly tender in its medio-dorsal region. Extremely restless; no dyspnea.

Diagnosis: Acute myelitis with softening, involving the entire thickness of the cord at a point in the lower dorsal region. The attack bore all the clinical characters of an acute inflammation from exposure to cold. He then suffered from a distressing sense of con-

striction about the body. On the fifth day of his sickness a strong faradic current was applied, one pole high in the rectum and the other over the abdomen, and an evacuation of the bowels obtained. In the third week there was notable atrophy of the muscles; and the level of the anesthesia was at the ensiform cartilage. There was fever throughout the course of the disease, and the patient lived two months after the first development of symptoms. A remarkable fact, relating to temperature, was that the temperature of the toes was higher than that of the body for the first few days.

Autopsy less than twenty-four hours after death: Enormous bed-sores over the sacral region. The spinal cord measured 12¼ inches from the point of section, in the lower cervical region, to the *filum terminale*. The lower dorsal region was the seat of marked swelling and evident softening. The cord was carefully hardened, first in absolute alcohol, and then in bichromate of potassa; and, when examined microscopically, presented the following lesions: Descending degeneration of the posterior lateral columns; ascending degeneration; nearly complete destruction of the anatomical elements at the seat of the greatest softening. Several ganglion-cells contained vacuoles; vacuoles apparently quite globular, and contents unaffected by reagents. The coats of the blood-vessels were thickened. Granular bodies—whether the granulation corpuscle or not, was undecided. Neuroglia thickened. Acute central softening.

Dr. Seguin discussed at some length the significance of the clinical history and its relation to the pathological lesions.

Dr. E. C. SPITZKA spoke of the remarkable and altogether exceptional rise of temperature, aside from that of the toes being higher than that of the body for the first few days; namely, the rapid rise which occurred immediately before death, with general rise of temperature in the whole body, showing that a sympathy existed between the physiologically separated portion of the cord and the entire central nervous system; and that the separated portion was endowed with a certain amount of vaso-motor influence.

The granular bodies to which Dr. Seguin referred he regarded as different from the ordinary granular pus-corpuscle, and deserved the name of granular cells. The so-called granular cells were frequently nothing but transverse sections of axis-cylinders with disintegrated myeline. He had noticed them especially in chronic myelitis. With regard to the explanation of the existence of these granular bodies, he supposed them to be leucocytes which had taken up a marked amount of pabulum in the shape of disintegrated myeline.

Dr. BRIDGALL asked whether the vacuoles were inside of the ganglion-cells, or outside in the perivascular spaces; and then followed a discussion regarding their meaning, the origin of spider-cells, etc.; after which, the Society adjourned.

INTERNATIONAL CONGRESS OF HYGIENE.—The third meeting of this Association will be held at Turin in April, 1880, under the patronage of the Italian Government. This Congress meets every other year, the previous sessions having been at Brussels and Paris. The work will be done in ten sections, which will include hygiene as applied to schools, to agriculture, manufactures, architecture, and so forth. The subject of regulating prostitution will also be brought up.

Correspondence.

MEDICAL ETHICS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In a correspondence published in your issue of Nov. 22d, Dr. Piffard, Secretary of the late Board of Censors, claims that your reporter was in error when he made the statement that the Censors reported that the Society lacked "legal power to take action with reference to certain cases of violation of the code," "as the careful perusal of the Censors' report will show." Your reporter has received the published minutes of the seventy-fourth annual meeting of the Medical Society of the county, which contain the Censors' report, and finds on page 31 the following consecutive sentences:

"The existence in this county of a considerable number of so-called regular physicians who are not members of this Society. . . . These gentlemen appear to enjoy the same benefits that the laws of the State intended should pertain only to members of county societies. . . . On the other hand, they are not amenable to the regulations of the Society, and many of them are beyond the reach of prosecution for breach of the code of ethics." Yours truly,

W. M. CARPENTER, Asst. Secretary.

SPEEDY CURE OF NASAL POLYPI.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The painless method of removing nasal polypi, never before made public by the originator, is an apology for taking a small space of your valuable journal.

Mr. G. M—, æt. 60, ten years ago applied to me for relief from a soft polypus in the left nostril. I proposed evulsion; but not liking the proposition, he left, and I never heard of him until last May, when he returned with another polypus in the same nostril. I advised evulsion once more; he declined it again, and desired me to cure him the same way as did Dr. G. Ceccarini the first time (ten years ago). On inquiry, Dr. C. kindly answered: "The medicine which I use for removing nasal polypi is four or five drops of pure acetic acid injected with an hypodermic syringe within the body of the polypus once only, very seldom twice; the polypus generally drops off within three or five days without discomfort or pain. Disinfecting lotion will correct the offensive odor." With this information, on the 12th of August, in presence of my friend Dr. J. L. Little, I injected the polypus with six drops of chemically pure acetic acid, and instantly we saw the discoloration of it from red to white. Business preventing him from returning, I could not observe the daily progress; but when he called on September 2d, he had only a small portion of it yet adhering to the middle turbinated bone, the other having dropped off the fourth day after the injection; this remaining portion was injected with four drops of the same acid, and on the third day dropped off, leaving his nose clear, without sore or a vestige of it. Neither of the two operations were followed by any unpleasant symptoms, save a slight smarting from the pricking by the needle when the acid was injected. The offensive odor arising from the decaying mass was corrected by a weak carbol-

ized wash. The long interval from the destruction of the first, and the appearance of the second—ten years between—precludes the possibility of this last being a portion of the first, but a new one.

Respectfully yours,
S. CARO.

ST. BARTHOLOMEW'S HOSPITAL.—The death of Mr. Callender leaves a vacancy on the visiting staff of St. Bartholomew's Hospital which will probably be filled by Mr. Willett, now senior assistant-surgeon.—*Brit. Med. Journ.*

LADY MEDICAL STUDENTS.—There are thirty-seven students at present in the London Medical College for Women, and the institution is considered to be in a very flourishing condition.

HOMŒOPATHIC INSANE ASYLUM.—Plans for the erection of the third building of the New York State Homœopathic Insane Asylum have been approved, and work upon it will at once be begun.

SCARLET FEVER IN ILLINOIS.—Owing to the scarlet-fever epidemic which is prevailing in Springfield, Illinois, the Local Board of Health has ordered the public schools to be closed until the 1st of January. They have also adopted a resolution recommending that no public funerals be held in churches or private residences. There are said to be about 500 cases of the disease in the city. It prevails in a mild form.

TESTING THE AUDIPHONE.—This instrument, which was described in our columns several weeks ago, has recently been subjected to some careful tests amongst deaf-mutes. It was found that some satisfactory results were obtained amongst the congenitally deaf; those in whom there was an incomplete development of the auditory apparatus rather than complete destruction of some of its parts.

THE NEW YORK FLOWER CLARITY.—This Society has, during the past summer, distributed over one hundred and forty thousand bouquets amongst the various charitable institutions of this city. We are glad to learn that the Society at times includes illustrated papers in its articles of distribution. It is to be feared that the average hospital patient prefers the Police Gazette to the most beautiful rose.

MOUNT SINAI HOSPITAL.—This hospital has recently received several large donations, among them one of \$25,000 from Michael Ries, of California. The hospital building has been renovated and repaired.

DETROIT MEDICAL COLLEGE.—The Detroit Medical College has adopted the three years' graded course of study, and an entrance or matriculation examination for all candidates for graduation. Each session is lengthened to six months. The new regulations go into force in the session of 1880-81.

TREATMENT OF GONORRHOEA.—In an article on gonorrhœa, Dr. G. W. Stoner, of the U. S. Marine Hospital Service, states that there is no one thing so useful as sulphate of zinc in the proportion of two or four grains to the ounce of rose-water. The mixture is still more effectual if an equal or somewhat smaller amount of tannic acid be added.—*Buffalo Med. and Surg. Jour.*

A THERAPEUTICAL CONGRESS.—In a paper read before the Canada Medical Association, Dr. Playter referred to the present lack of uniformity in therapeutical teaching and practice; he spoke also of the indefinite and often contradictory opinions that still prevail in regard to the properties of many drugs. In order to remedy this unsettled condition of affairs, it was proposed that the various medical associations in this country and Great Britain—and other countries, if possible—appoint committees, who should meet in a general conference and try to secure some more uniform and harmonious conclusions upon the subject, especially of therapeutics.—*Canada Lancet.*

DR. WILKS, of Guy's Hospital, has been appointed physician to the Duke and Duchess of Connaught, in succession to Dr. Murchison, deceased.

MEDICAL RESEARCHES.—About \$15,000 was appropriated by the British Medical Association at its last meeting, to aid in prosecuting various medical researches. Among the special objects are: \$250 given Dr. F. Ogston, for the research into the relation between bacteria and surgical diseases; \$250 to Dr. McKendrick, for investigation on anesthetics; \$120 to Dr. Crocker, for researches upon the physiological action of alcohol, with special reference to its elimination, etc.

In this way the money has been dealt to about a dozen eminent men, who will investigate and make reports upon the subjects assigned them.

The plan is certainly an admirable one, and deserves imitation with us.

DIPHTHERIA EPIDEMICS.—A very violent form of diphtheria is reported to have broken out in the country about London, Ontario. It is known, locally, as "black tongue."

A remarkable story from Vermont, concerning the spread of diphtheria is going the rounds, and seems to be pretty well vouched for:

A few weeks ago a family of three children in St. Albans, Vt., had the diphtheria, but made good recovery. After they had been well and about the

streets for two weeks, they went to Fairfield and visited in four families. At that time there was no diphtheria in Fairfield, but since then it has broken out in each of those four families.

The ravages of diphtheria in Russia have for several years been very great. It is reported that this fall the disease has continued to increase. In Odessa, since May last, 76 per cent. of the children have died from the disease. In other places half the infant population has perished in the same way. Eleven districts in all are now infected, and the condition of affairs is so serious that the government has appointed a special commission to investigate the causes of the epidemic.

PRURITUS VULVÆ.—Dr. S. L. Parmelee, of Watertown, N. Y., writes: My attention has been called to an interesting case reported by Elizabeth M. Cushier, M.D., in the last Record of November 8, 1879, of an epithelioma of vulva, and she asks the question if the long-existing pruritus could have had any relation as cause for its appearing, or whether the removal of it by operation could have produced such changes as to cure the pruritus.

In alluding to the case, I only wish to draw attention more directly to the pruritus vulvæ, its general cause and cure.

In my mind, in the case reported we have a not uncommon cause in the condition of the cervix which was found. The patient, although sixty years of age, had "the membrane of cervix of a deeper color than the vaginal membrane, and a slight erosion, and a small amount of thin yellow fluid (sero pns) escaping from the cervix with a sensitiveness of the canal on the passage of a probe."*

Do we not have here the true cause of the pruritus and the real cause of its cure, the very appropriate applications of carbolic acid and glycerine to the cervical canal?

The relics of an old cervical leucorrhœa remaining so long after the menopause, although very slight, might produce, by its irritating character, this pruritus; but what is very likely a more rational explanation, the reflex irritability of the sensitive nerve filaments might have produced it, as we well know that pruritus is oftentimes a pure neurosis. Bearing upon this reflex irritability, caused by a morbid condition of the cervical canal, lingering sometimes long after the menopause, I will give a single case:

Mrs. R—, aged fifty-two years; menses ceased some four years previous, and whose general health was excellent, except somewhat frequent attacks of severe strangury, for which her husband, a retired physician, had canterized the urethra locally with appropriate internal medication; but all to no avail. At his request, I called upon her, and a vaginal examination found the uterus very much atrophied and the external os almost entirely closed; but after close examination a minute orifice was found at the bottom of the vaginal cul-de-sac, and upon passing a very fine probe, I found the original cervical canal so sensitive that great pain was caused by its passage, which reminded me of the sensitive crown of a tooth.

Dilating the external os and making a few applications of tr. iodine, she was completely relieved of her long-standing and painful malady.

With one or two inquiries, I will close. Are there not many times conditions of nervous system that linger years after the "change of life" which ought

* Italics mine.

not to be referred to some lingering old uterine trouble, and which is too often overlooked? And is it not our duty to keep constantly before us this fact in many maladies after this change has occurred?

A DOCTOR NOT IN CONSULTATION.—It has never been thought necessary to teach the differential diagnosis between typhoid fever and strangulated hernia; nevertheless, a melancholy instance of where such instruction was needed occurred at Pennsylvania last month. A young man, aged 23, was taken with chills, and continued to grow more and more ill. Two physicians, Drs. A. and B., were called in to see him, and pronounced the case one of typhoid fever. They treated him for this disease for some days, but the patient grew steadily worse, and at last the family, unknown to either of the first two physicians, called in Dr. C. He stated that the treatment which they had been following was entirely wrong, and that the patient was suffering from strangulated hernia. He gave a hypodermic injection of morphine. After this the patient grew drowsy, fell into a heavy sleep, and, in a few hours, died.

The coroner made a post-mortem examination, and found that the disease was typhoid fever, as had been first diagnosed. We do not know whether or not Dr. C. has heretofore been considered an ornament to the medical profession. In his connection with the above case, there was a positiveness of statement and a decision of action which, on previous occasions, may have won him much favor. His last performance, however, makes it clear that his proper sphere of usefulness is outside of the professional line. Violations of the code of medical ethics are known to have been overlooked; insinuations against the character of a professional brother have been condoned; and even extremely stupid mistakes are known to have been committed by very respectable practitioners. When, however, all these three derelictions occur on one occasion, and to one man, he should be requested, for the sake of humanity and our common reputation, to step out from the ranks of medical men.

It is instances of this kind which show that our code of ethics has a practical value, as well as an aesthetic and moral one. A proper consultation in accordance with rule would have saved much distress, and, perhaps, a fatal issue.

POP-CORN IN THE NAUSEA OF PREGNANCY.—Dr. F. A. Burrall, of this city, writes: "One of the best remedies for the nausea which attends the parturient state is the quickly roasted grain of the *Zea mays* or Indian corn. It is too familiarly known as 'pop-corn' to require any description. Many physicians are not aware of the beneficial results which may often be derived from the use of this simple agent. It should be white and light, and may be eaten freely, sprinkled with salt. I think it is no exaggeration to say that it will be found of the greatest service in many cases where the products of the chemist's art have proved unavailing."

A ROYAL SANITARY COMMISSION has been appointed to go to Dublin and investigate the condition of matters there. For a long time that city has had the reputation of being wretchedly drained and cleansed, its tenement-houses being particularly bad.

PHARMACEUTICAL USE OF GELATINE.—According to the *Pharmaceutical Journal*, gelatine is not suitable as a vehicle for tannin in pessaries or suppositories. A decomposition occurs with the formation of tannate of gelatine, and the otherwise gelatinous vehicle breaks down in the preparation. As it is becoming

fashionable to use gelatine as the vehicle for various drugs, and especially to prescribe pessaries of this material, the fact thus noted should be borne in mind.

THE MEDICAL LAW OF CALIFORNIA.—Several of our Western States have taken the lead as regards legislative restrictions upon quackery. Of these States, California, according to the *Western Lancet*, heads the list. The editor of this journal, in commenting upon the workings of the law, states that, although not rigidly enforced, it has already done a great deal toward driving away notorious quacks and impostors. The law has been pronounced constitutional by the highest tribunals, and, as a rule, convictions follow the cases of arrest. In that State, to be an unlicensed doctor is to be a law-breaker.

IRREGULAR PRACTITIONERS ON HEALTH BOARDS.—Encouraged by their success in getting on the National and other boards of health, a petition has been signed and sent to Governor Blackburn, of Kentucky, asking that a homœopathic doctor be made member of the State Board of Health. It is thought that this effort will surely fail with the doctor-governor.

SANITARY INSTITUTE OF GREAT BRITAIN.—This organization held a meeting at Croydon under the Presidency of Dr. Richardson, on Oct. 21st, 22d, 23d, and 24th. There was a sanitary exhibition in connection with the meeting, which was the largest and most influential ever given in connection with the institution. Papers were read by a number of prominent sanitarians.

THE MASSACHUSETTS MEDICAL SOCIETY has voted to admit women to membership. As Boston female doctors largely run to homœopathy, it is not expected that the society's action will greatly change the character or sex of its members.

TO REMOVE PLASTER-OF-PARIS FROM THE HANDS.—A very effectual way of removing plaster-of-Paris from the hands, is mentioned by a correspondent of the *Boston Medical and Surgical Journal* as being employed in St. Thomas's Hospital. It consists merely in the use of white of egg, instead of soap, in washing the hands. The fact will interest those who have much to do with plaster dressings.

NATIONAL ACADEMY OF SCIENCES.—At the recent meeting of this Society in New York City, Dr. J. J. Woodward presented the results of some of his work in connection with the production of the "Medical and Surgical History of the Rebellion." This work referred especially to dysenteric and diarrhœal diseases.

Dr. J. C. Dalton presented some generalizations upon the structure of the human brain. He showed, in particular, that the gray matter of the cerebro-spinal system is in three deposits: viz., in the centre of the cord, in the ganglia at the base of the brain, and in the cortical substance. These three deposits are all intimately connected. The true shape of the corpus striatum and the relations of the hemispheres to the crura cerebri were also described.

SURGEON-GENERAL P. S. WALES, U. S. NAVY.—Surgeon-General William A. Hammond, U. S. Army (retired), of this city, on the evening of November 20th, gave a brilliant reception in honor of P. S. Wales, of the U. S. N., lately appointed Surgeon-General. A large number of members of the clerical, legal, and medical professions, and also several eminent representatives of the U. S. A. and the U. S. N., were present.

Original Lectures.

CLINICAL LECTURE ON DISEASES OF WOMEN.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

By T. GAILLARD THOMAS, M.D.,

NEW YORK.

[Reported by P. BRYNBERG PORTER, M.D.]

CASE I.—*Pelvic Neuralgia due to Laceration of the Cervix.*

GENTLEMEN:—Our first patient to-day is Bridget R—, a native of Ireland, and thirty-one years of age. She has been married twelve years, and has had six children and one miscarriage. The last child was born three months ago, and (as we so often find the disorders peculiar to women dating from parturition) she informs me that her trouble has lasted just three months. What she complains of, and has come here to seek relief for, is a fixed, constant, and severe pain in the lower part of the abdomen, which has continued ever since her child was born. She suffers from absolutely nothing else whatever, and is, as you perceive, a perfectly healthy-looking Irishwoman.

The pain is certainly a very definite reality to her, and yet, when I came to make external palpation over its seat, as indicated by her, I found nothing at all abnormal about the locality, and no tenderness was excited even when very firm pressure was made upon it. In order to find out, if possible, what it was due to, I made a vaginal examination, the patient in the meantime informing me that she had been previously examined by a physician, who told her that she had "ulcers on the womb." As soon as my finger reached the os, I found that there was a very bad laceration of the cervix, extending fully up to its junction with the vagina; and this was no doubt the explanation of the ulceration which was supposed to exist in the case. Besides this, there was nothing abnormal about the pelvic organs, as far as I was able to ascertain, except that the uterus was tilted slightly forward.

Now, have we arrived at the diagnosis in this case? I think we have; for I am fully convinced that the constant pain complained of here is really a reflex neuralgia, which is due to nothing else but the pathological condition found about the cervix. But you say: Have you not told us that the uterus is anteverted to some extent? Yes; but that condition, too, I believe to be due to the laceration of the cervix also. The laceration has been the means of keeping the uterus constantly engorged with blood, and consequently, being heavier than it ought to be, it has fallen forward somewhat, and remained in this position.

This completes the case, with the exception of a brief allusion to the treatment. Since this reflex neuralgia depends, as we believe, upon the laceration, the only way to cure it is to perform an operation and close the latter. If our diagnosis is right, it is just as sure to do away with the pain complained of as the removal of a tooth is to cure a supra-orbital neuralgia which depends upon its presence in the mouth. In either case the suffering may not cease at once, but, the cause having been really removed, it will, at all events, gradually disappear. If the operation for the closure of the laceration is performed here, I am

confident that the patient will be entirely relieved of all her pain. The focus of irritation will then have been removed, and the uterus will also return to its normal position, because the cause of its congestion will have disappeared.

This is not an isolated case. If it were, I should not be so willing to attribute the whole trouble to a laceration of the cervix (although here very extensive); but I have seen such a large number of similar instances in which complete relief was afforded by the operation, that I can speak with a considerable degree of confidence.

CASE II.—*Chronic Ovaritis.*

The next patient, like the last one, I want to use for the purpose of impressing a fact upon you. The advantage of a clinic like this I conceive to be that you here see cases which will be of advantage all through your practice when you meet with similar ones. Thus, for instance, when in three, five, or ten years from now, you see a patient whose only symptom is such a reflex neuralgia as is present in the case that has just been dismissed, the memory of this laceration of the cervix, long forgotten it may be, will instantly flash across your mind.

The patient's name is Margaret B—. She is a native of the United States, twenty-five years old, and single. "How long have you been sick?"

"About two years."

"Were you quite healthy up to that time?"

"Yes."

"In what way have you suffered?"

"From severe headache and pain in the back and side."

"In any other way?"

"No."

(These are, of course, obscure symptoms; but still they point towards the generative organs, and are sufficient to induce us to ask direct questions concerning them.) "How about your monthly periods?"

"I have great pain then."

"At what time does the pain come on?"

"A week before the blood comes."

"Do you suffer much at this time?"

"Yes, very much indeed."

"Where do you feel this pain, of which you speak?"

"All around the waist."

"Is there any particular point where it is especially severe?"

"Just here" (placing her hand over the left iliac fossa).

"And does this keep you very uncomfortable?"

"I can get no rest at all."

(I assure you, gentlemen, that this patient is not exaggerating in the least; for, as she described them to me in private, her sufferings are undoubtedly much more acute than she gives you any idea of here.) "Is it a full week before the flow that the pain commences?"

"More often about five days."

"When the flow comes on, does the pain cease?"

"Yes."

(Yet this is called dysmenorrhœa. You see, however, how utterly inapplicable the term is in such a case as this. Dysmenorrhœa, of course, means difficult menstruation; and yet here the patient only gets relief when the menstrual blood begins to flow. This is the peculiarity about these cases, although the relief when the flow comes is not always complete. Let us inquire about this point here.)

"When the flow appears, does the pain stop altogether."

"Usually it does, but sometimes I have pain for about three days longer."

"Then how is it with the last two or three days of your period?"

"I am entirely free from pain then."

"Do you have the whites at all?"

"A little."

This is a typical case of its class. Here is a woman who evidently has something wrong about one of the processes, either of ovulation or menstruation. You know that in the last few years many authorities have begun to doubt that ovulation is really the cause of menstruation. In support of the view that they are independent processes, it has been claimed that a number of instances have occurred in which both ovaries have been removed, and yet menstruation has gone on just the same as before. In matters of this kind, however, one cannot help being guided to a certain extent by his own experience. I have taken out both ovaries in no less than fifteen cases, and yet in not a single one of them has the patient continued to menstruate. In two or three, it is true, there was a tendency to metrorrhaxis, as it is called, which is analogous to epistaxis. But this was due, undoubtedly, to the habit of menstruation which the uterus had acquired during a long series of years, and could not give up all at once. In every instance, however, the menses disappear altogether in the course of a few months. In one instance that I know of (not in the human subject, however), I must confess that I was not a little puzzled for a time, as it was so contrary to my experience. A bitch which had been spayed continued to estruate just the same as before. But when after a time she became pregnant and gave birth to pups, the whole matter became clear. Although both ovaries had been completely removed, there was undoubtedly present in this instance a supernumerary ovary (the *ovarium succedaneum*, as it is called), which is occasionally met with in the lower animals. If the animal had not happened to become pregnant, the case would certainly have been quoted as one of those supporting the idea that menstruation is independent of ovulation; but as ovulation took place, it was evident that there was still an ovary left, which, of course, would account for the menstruation as well as the ovulation. The arguments of those maintaining the independence of the two processes, are, in my opinion, weak and inconclusive. My impression is that menstruation is dependent on ovulation; and I am convinced that in time we will all go back to the unchallenged faith of our fathers.

In the case now before us, the derivative action of the menstrual flow always relieves the pain that precedes it, and, as a general rule, dissipates it entirely. What, then, would seem to be the trouble here? Something must be wrong about the ovaries, and in all probability the left one particularly. At all events, this would satisfactorily account for all the symptoms which have been noted, as well as one additional one to which the patient has just called my attention, and which has not as yet been mentioned to you. This is a peculiar dusky discoloration of the skin upon the forehead, similar to that seen in Addison's disease, and giving a sunburst hue to the part. Such a pigmentation is generally of long standing, and sometimes becomes permanent.

On resorting to a physical exploration here, the first thing that I noticed was that the uterus was decidedly anteflexed. Now, if any one had made the

vaginal examination without first inquiring particularly into the history and rational signs, as we have done, he would undoubtedly have pronounced this a case of obstructive dysmenorrhœa, due to anteflexion of the uterus; and I cannot tell you how often I have known even eminent surgeons cut deeply into the cervix, for the purpose of relieving stricture at the *os internum* in just such cases as this. Yet, what could possibly be more illogical? In the first place, the pain occurs long before there is any blood in the cavity of the uterus to be dammed up by the obstruction at the *os internum*; and, in the second place, as soon as the blood makes its appearance, the pain is at once relieved, or even done away with altogether.

I was therefore satisfied that this was by no means the true diagnosis of the case; and, proceeding with the examination, I succeeded in finding just what I expected to find from the symptoms which the patient had so feelingly described. On making conjoined manipulation, I ascertained that there was nothing abnormal in the region of the right ovary; but in the left broad ligament I discovered a body about the size of a hen's egg, and so exquisitely sensitive that the slightest pressure upon it caused the patient a great deal of suffering. Indeed, as soon as I began to palpate it, she exclaimed, "That is what gives me my headache and all my trouble." Now, I felt that I had arrived at the correct diagnosis, and this was *chronic ovaritis*.

This condition is vaguely so called, for we know almost nothing of ovarian pathology, except so far as cysts and other large tumors of the ovary are concerned. The only way to find out the exact state of affairs would be by a section of the organ; but, as this affection never proves fatal, there has been very little opportunity for studying its real pathology. The most that we can say concerning it is that there is probably a certain amount of hyperplasia present, and certainly congestion and nervous derangement. But how about the displacement that we find in addition to the chronic ovaritis? This is a coincidence that you must always be prepared to expect; and Barnes, in his work on diseases of women, makes the unqualified statement that there is more or less displacement of the uterus in every case of chronic ovaritis. The explanation is that the uterus is kept constantly engorged with blood, in consequence of the condition of the ovary, and hence, being much heavier than normal, it bends over in one direction or another, and then remains permanently in a malposition. It is possible that in the healthy female the uterus not infrequently falls backward or forward at the time of the menstrual epoch, in consequence of its increased weight at this period; but, the congestion being only temporary, the organ returns to its normal position as soon as that passes off. The leucorrhœa that has been noted in this case is also probably due to the same cause, the long-continued congestion of the uterus having given rise to endometritis, or chronic uterine catarrh.

The prognosis in such a case as this will depend somewhat on whether the medical attendant directs his treatment to the uterus alone. If you should pursue this course, at the end of a year or two, perhaps, the patient will complain that she suffers exactly the same, not having experienced the slightest relief, even though her uterus may have been restored perfectly to position and constantly maintained there. Why so? Because you will have been treating merely an effect, and not the cause of the trouble. What should be treated is that left

ovary; but, alas! our means for doing this are extremely limited, and far from satisfactory. Such a condition as is here present will yield only to a prolonged course of treatment, and in some instances will not yield at all. Many of the cases are so incurable that the only chance of relieving the patient is to resort to the operation which Dr. Batty has devised, and termed "normal ovariectomy." It is, however, such a dangerous procedure that it should never be undertaken unless the case is really a desperate one.

Notwithstanding that these cases are so discouraging, however, I should certainly advise you never to begin with one of them by telling the patient that you can do nothing for her. Such an announcement would only utterly dishearten her, and if it did not plunge her into a permanent state of melancholy, would, at all events, tend to make her feel worse than ever. One thing that you always find about them is that the general condition is considerably impaired; so that, in the first place, the patient needs feeding up to the greatest possible extent, in addition to a course of appropriate tonics. One of the best that I have found in this condition is the syrup of the hypophosphites, which is now so frequently employed in the incipient stages of phthisis; and iron, quinine, and other agents, will all prove of some service. The remedies employed should always be changed from time to time. But in order to produce a beneficial effect upon the nervous system, I know of nothing whatever so useful as what is called "travelling for pleasure;" and, if this patient could spend a year in Europe, under agreeable circumstances, I have not the slightest doubt that she would be immensely benefited. I have found no other treatment for chronic ovaritis nearly so good as this change of air and scene, and the pleasurable excitement of sight-seeing and travel in cheerful company, although I do not pretend to explain exactly in what manner the good result is brought about.

But, supposing that the patient is not able to travel in Europe, what can we do for her in addition to giving her the tonics spoken of? In the first place, she should be directed to make use of very copious hot-water vaginal injections at least twice a day, and three times, if possible. Then I should paint the roof of the pelvis once a week with compound tincture of iodine; but if after a time it was found that this was not doing her any good, it ought to be discontinued; after which it would probably not be necessary to make another vaginal examination for several months to come. Iodine might also be applied externally, and as often as two or three times a week. At the same time electricity should be faithfully employed, and for this purpose I have found the constant current the only one that is of service, the faradic current being rather injurious than beneficial. The best way to apply it is for the patient to lie upon one electrode while the other is carried to the region of the affected ovary, and the application may be made once or twice a week. For at least a week preceding menstruation the patient should have absolute rest in bed (rest being as important to an inflamed ovary as to an inflamed eye); but she may be permitted to get up as soon as the flow makes its appearance.

Under such a plan of treatment I should expect the patient to be materially benefited in the course of a year, and it is possible that she might be very greatly improved even in a few months. Under ordinary circumstances, of course, it is impossible for a girl like this to have such measures as these carried out; but if she can be persuaded to enter such an institution

as the Woman's Hospital in this city, I can assure her that everything will be done for her that science can suggest for the relief of such unfortunate cases.

CASE III.—*Menopause unusually delayed.*

Our next patient, Elizabeth C—, was born in England, and is fifty-one years old. She has been married thirty years, and has had thirteen children and two miscarriages.

"How long have you been sick?"

"Ten months."

"Not longer than that?"

"Yes, somewhat; but I commenced doctoring about ten months ago."

"What was it for which you consulted the doctor?"

"Bloating of my stomach."

"Anything else?"

"Pain in the back."

"If the bloating of your stomach were gotten rid of, you would feel quite well, would you not?"

"Yes."

"When did you have your monthly sickness last?"

"Seven weeks ago."

"How many times have you had your sickness during the last twelve months?"

"Four times."

"Do you have any discharge?"

"Sometimes a little whites."

In glancing back on this history, we find the symptoms quite obscure; but, at all events, we have the interesting fact that this woman of fifty-one has not altogether ceased menstruating. During her fifty-second year, as we have seen, she has menstruated four times; and on inquiry I find that during the year preceding she menstruated more frequently than she should have done, the flow occurring regularly every three weeks. For a year past she has noticed a considerable enlargement of the abdomen, which she calls "bloating;" and she now informs me that this causes her a great deal of difficulty in breathing when she takes exercise. As she expresses it, it "all smothers her up." She appears to have no other trouble.

On making an examination *per vaginam*, I found that the uterus measured three inches in depth, and although this was by no means a long measurement for the uterus of a woman who has borne thirteen children, I ascertained, on making conjoined manipulation, that the uterus was larger than normal in other respects. I also discovered a very extensive laceration of the cervix, which must have been made during one of her labors (perhaps the first), and was, no doubt, the cause of the sub-involution of the uterus here noticed. This state of affairs would, it seems to me, account for the patient's still menstruating at the age of fifty-one, the physiological atrophy at the ordinary age of forty-five having thus been prevented. There is, however, no disease about the structure of the organ; and it is probably smaller than it was a year ago. The near approach of the menopause is also indicated by the marked diminution in the frequency of menstruation.

One characteristic of the change of life, as it is popularly called (especially when this comes on at a later period than usual), is senile hysteria; and accompanying this is a very marked tendency to tympanites. This tympanites is exceedingly apt to come on at the time of the menopause, and is, indeed, often seen in cases where there is none of the hysterical element in connection with it. In the present instance you notice how very resonant and drum-like the sound is when I make percussion over the dis-

tended abdomen. This accumulation of gas no doubt presses upon the diaphragm to some extent and causes the patient a certain amount of discomfort. So much, then, for the diagnosis.

As to the prognosis here, I may remark that no remedy at present known to medical science will cure the tympanites. A frank and kindly talk on the part of the medical attendant will do more for the patient in such a case as this than all the medicine in the world. Such women are apt to imagine that they are the subjects of tumors and all sorts of terrible affections, and it will do them a great deal of good if they can be made to understand that the whole trouble is due merely to wind in the intestinal tract, and that the utmost injury that it can cause them is simply a little inconvenience. The tympanitic condition is due entirely to the state of the nervous system peculiar to this period of life, and nothing need be done for it except to keep the bowels regular. In the present case, there is no constipation, and the patient, therefore, requires no medicine. In some instances systematic kneading of the abdomen is of service, and the knee-chest position will often enable the patient to get rid of a considerable quantity of the gas. Dr. Jenks, of Detroit, has recently written a very interesting paper on the treatment of tympanites by this postural method, and although it is a plan of treatment that has long been recognized to some extent, he deserves great credit for calling the attention of the profession to it in so able and forcible a manner. There is one case which he mentions particularly, in which such marked tympanites came on after ovariectomy that the patient nearly died in consequence of it. When this method was resorted to there was an escape of an unlimited amount of flatus by the anus, and the patient afterwards made a good recovery from the operation. Personally I have been in the habit of employing it in certain instances for the past fifteen or twenty years, and can, therefore, confidently recommend it to you.

CASE IV.—*Pregnancy, with Ante flexion of the Uterus.*

Our last patient to-day is Mary C—, a native of the United States, and twenty-two years of age. She has been married five years, and has had three children and one miscarriage. Her last child was born one year ago, and the miscarriage occurred before that.

"How long have you been sick?"

"One year." (The patient has been sick just a year, and, as you have heard, it is just a year since her child was born. Here, no doubt, is another of these very frequent instances that we meet with, in which injuries received by the uterus in parturition give rise to long-continued trouble afterwards. In the case of the woman who was just before us, for instance, I am confident that the unusual delay which we found in the menopause was due to the subinvolution of the uterus that remained after one of her labors.)

"In what way do you suffer?"

"I have the back-ache."

"Do you have pain anywhere else?"

"No."

"Do you suffer from the whites?"

"Yes."

"Very much?"

"Yes."

"Do you have any trouble with the bladder?"

"I have to pass my water very often."

"Are you regular in regard to your monthly sickness?"

"I have not seen it for two months."

"You do not think you are in the family way?"

"No."

When I made an examination here, I at once discovered that the uterus was bent over, and directly pressing upon the bladder. Here, then, already was a sufficient cause for most of the symptoms; the frequent urination, the back-ache, and the uterine catarrh giving rise to leucorrhœa. But, on touching the cervix with my finger, I found that it was quite soft and covered with a tenacious fluid; and when I employed conjoined manipulation, ascertained that the uterus was more than twice as large as it ought to be.

Why was the cervix so soft and the uterus so large, and why had the menses stopped for two months? I could come to but one conclusion, and that was that the patient was pregnant. In all her previous pregnancies she has suffered markedly from nausea and vomiting, and the absence of this sign made her think that she could not be in this condition. This symptom, however, is by no means a constant one, even in women who are ordinarily subject to it; although just why it should sometimes be present and sometimes not, it would be difficult to explain.

But now, if we find, as I should be almost willing to assert from the absolutely healthy appearance of our patient, that this young woman has never in her life skipped a monthly period unless she was either pregnant or nursing, it would be strong additional evidence that she is now again pregnant. On questioning her, I learn that this is actually the fact, and therefore I do not hesitate to make the diagnosis of pregnancy here. You remember (as I have before endeavored to impress upon you) that a diagnosis is the most logical deduction that we are able to draw from the premises in any given case. Let me advise you in this connection never to be afraid of making a mistake. Always do the best you can under the circumstances, and no one can reasonably find fault with you. There are some men so timid that they are never willing to risk an opinion; but such individuals are invariably weak men, who will never make any success in life. It is possible that in a month from now this patient will come back, and I will find that she has not been pregnant at all; but if this is the case, it will not be the first mistake of the kind that I have made. Like every other medical man of any experience, I have made a large number of mistakes in diagnosis; but, as in every instance I have endeavored to draw the most logical conclusion that I could from the premises offered, I do not think that I have any reason to reproach myself on this account.

Let us glance again at the premises in this case. Given a perfectly healthy woman, who, in the first place, has never skipped a period except during pregnancy or lactation, and who has now seen no menstrual flow for two months; who, secondly, has a softened cervix uteri (which, by the way, admits the finger; while in the normal cervix the *os externum* will only permit the passage of the uterine probe); and who, finally, has a uterus which is more than twice the natural size of this organ, and has lost the natural distinctness of outline characterizing it. What is the deduction? Plainly, that the woman is pregnant; and this is the only common-sense conclusion that can be arrived at under the circumstances.

As to the ante flexion (which, of course, accounts for the marked irritability of the bladder), that, no doubt, originated at the time of her last delivery, a year ago. Either she got up too soon after the labor (which is very probable), or something else occurred

then which resulted in this displacement. Notwithstanding the latter, however, and the consequent bent condition of the uterine canal, seminal fluid seems to have made its way into the cavity of the organ, and the woman is again pregnant. The only thing which I would suggest for the relief of the displacement here would be a cork pad (which I am in the habit of advising, on account of its cleanliness), which should be worn upon the lower part of the abdominal walls, in order to lift up the fundus of the uterus. This, I think, will be a great comfort to our patient, and I will only ask, in conclusion, that she will do us the favor of coming back here in a month from now, so that we can have the opportunity of verifying or disproving the diagnosis which has been made.

Original Communications.

NERVOUS DISEASES CONNECTED WITH THE MALE GENITAL FUNCTION.

By GEO. M. BEARD, A.M., M.D.

(Continued from p. 295, Sept. 27, 1879.)

NERVOUS SYMPTOMS CONNECTED WITH TRUE SPERMATORRHOEA—TRUE AND FALSE HYPOCHONDRIA.

IV.

HALF a century ago, when women consulted their physicians for symptoms of pain in the back, difficulty of micturition, bearing-down sensations, pain in the vertex and other forms of head pain, insomnia and malaise, with mental depression, incapacity and indisposition for labor, the diagnosis for hysteria was almost always made. At the present time, a female with these symptoms, and other symptoms often associated with them, is submitted to examination by the gynecologist, and, in very many cases, there is found a diseased condition of the reproductive apparatus—congestions, displacements, and the like; and no treatment of these cases is regarded in any sense as scientific where such examination is not made, and where the proper local treatment is not employed. Whatever constitutional treatment is used; local treatment is considered indispensable—and, on the part of some, has been carried to an extreme, to the rejection or neglect of constitutional treatment. In this respect there is now a reaction; by truly scientific physicians, both constitutional and local treatment are used in alternation or succession.

The functional nervous diseases of men are now in the same condition as the diseases of women half a century ago. Symptoms of mental depression, morbid fear in all its types and phases, hyperidrosis, nervous dyspepsia, palpitation, deficient mental control, together with various forms of head, back, and body pain, are all referred to hypochondria; and there is usually no thought of referring any of these symptoms to the reproductive system, on which they often depend. In the future it will be understood—indeed, it is beginning to be understood now—that the diagnosis of hypochondria in these cases is oftentimes as unscientific as the diagnosis of hysteria with analogous symptoms in women; that whatever constitutional treatment be employed, there should go with it simultaneously, alternately, or successively, local treatment, especially to the prostatic urethra,

which is so often the source whence all these difficulties originate, and by which they are maintained.

This view of the relation of the reproductive system to nervous disease is not narrow or one-sided, nor does it partake of the character of a hobby; neither is it here pushed in any way to an extreme. It is in accordance with facts that are verifiable and abundant, that in men as in women, a large group of nervous symptoms which are very common indeed, would not exist but for morbid states of the reproductive system.

I knew of a case of prolapsus uteri where the patient was kept in bed for two years, and treated constitutionally for various symptoms, without any examination ever having been made or suggested; as soon as she fell into proper hands, she was treated by mechanical means, and at once relieved.

We censure, in the strongest words we can command, a physician who manages a case of female disease in this way, at the present time, because the teaching of the schools is clear and abundant, and general practitioners, as well as special practitioners, are expected to recognize, and do recognize, the nervous symptoms of women that suggest disorder of the reproductive system.

When the relation of nervous diseases to the male genital apparatus is as well understood as their relation to the female genital apparatus, it will be regarded as an oversight of a serious character not to inquire and examine, as far as possible, into this local condition, when certain nervous symptoms appear.

What lacerations of the cervix and perineum, irritations, congestions, and displacements of the uterus and ovaries, are to many female nervous symptoms, such are phimosis, redundant prepuce, varicocele, irritable testes, urethral contractions, and, above all and pre-eminently, irritations and congestions of the prostate and *prostatic urethra*, with spermatorrhœa, to many male nervous symptoms.

Interesting and important as have been the advances by surgeons in the surgery of the male genito-urinary organs, the nerve-relations of these parts and functions now remain in little the same state that they were in the days of Lallemand.

The following cases illustrate both the importance of making examination of the reproductive apparatus when certain nervous symptoms exist, and the results which follow neglect of such examination, and consequent want of knowledge of the real source of the difficulty. The cases are the more interesting from the fact that both of them were scientific men, experts in the strict sense of the word, and well qualified to observe and report upon the symptoms. Both of them, I may say, co-operated with me in the study of the cases, and with scientific interest—through the intellect more than through the emotions.

CASE XVII.—A young man, not quite thirty years of age, gave me this history: He had formerly been troubled with great pain in the lumbar spine, which had persisted for some time, but which had been relieved some years before by stretching of the prepuce, for a degree of phimosis that existed. The relief which followed this operation for this special symptom of lumbar pain was interesting, and, in his case, I think was not due in any way to mental influence.

When he consulted me he was troubled at times with inequality of the pupils; but this symptom was not constant as in organic disease of the spine, but came and went, like other symptoms of sexual neurosthenia.

He suffered at times from attacks of nervous chills,

with depression. He likewise suffered from fear of society, so common in these cases.

With all this there was an incapacity and incompetency, at times, for his work, which was confining and exacting, and the query arose whether he ought to continue in his profession. Being a thorough expert with the microscope, he had made very many examinations of urine; and, but a short time before seeing me, he had examined his own and found that it contained spermatozoa. This was a surprise to him; but subsequent examinations confirmed this analysis.

For years this individual had been in a state of chronic exhaustion without suspecting that spermatorrhœa might be an accompanying, if not a causative factor. Even allowing that this unnatural flow of semen in the urine or at stool is, in some instances, an effect of the general neurasthenia, it is surely important to know of its existence. Regarding it as a symptom only, it is a symptom to be noted and treated.

This case was put under both local and general treatment, and is improving.

CASE XVIII.—A physician in middle life, of very fine organization, of marked nervous diathesis, consulted me for a group of nervous symptoms from which he had suffered seven or eight years. The symptoms were pain in the upper part of the back and shoulders, mental depression, insomnia, and shooting pains resembling ataxia. The bladder was exceedingly irritable; putting the hands in cold water caused the urine to flow; on any excitement also there would be discharge—the weeping penis.

He was troubled also with a great dread of company, especially that of strangers; but, by taking great care of himself, was able to attend to a very large practice; though he was easily prostrated by over-exertion or by mental disturbance. Seven years before he had lost his wife, and had not married again. The urine was examined by Dr. Mittendorf, and found to contain a quantity of spermatozoa. This was somewhat of a surprise to the patient, who is himself an accomplished diagnostician; though at the same time it confirmed his suspicions.

Involuntary emissions had annoyed him before marriage, and had recurred after the loss of his wife seven years before. At times, as is quite frequently noticed in these cases, the penis and scrotum were cold to the touch.

How long the spermatorrhœa had existed in this case can never be known; but as the nervous symptoms had been troubling him for years, it is not probable that the spermatorrhœa was a new complication.

On using the different kinds of local measures that have been referred to in other papers of this series, it was found that the urethra was very irritable indeed, and that unusual caution was needed in the introduction of instruments and application of remedies. Mild electrolysis of the prostatic urethra, and faradization with sounds, being almost the only forms of direct local treatment that were well borne. An urethra in this irritable state is a perpetual source of reflex irritation, for the body: it sets the whole system on fire like an irritable uterus or ovary in woman, and produces very many of the same symptoms.

It seems almost impossible to tell, from the nervous symptoms alone, whether spermatozoa will or will not be found in the urine on examination.

In the following case there were even more symptoms which suggest trouble with the prostatic urethra than in the two preceding cases; and yet, on an examination of the urine, there was found only an

cess of phosphate of lime—there was not even excess of oxalates and urates.

CASE XIX.—The patient, a young man thirty years of age, had the following symptoms: stiffness of the lower limbs; very much pain in the lumbar spine, in the back of the head and neck, feeling of pressure at the vertex; heat in the spine; soreness of the bottom of the feet—sometimes the heel would feel as though it were a bare nerve; the gums were tender and white; the pupils were dilated; he had nervous dyspepsia; the feet and hands at times were very cold, especially while thinking; the power of mental application was impaired; he was annoyed with ringing in his ears and insomnia, stomachic vertigo, and vomiting; and he had anthropophobia, or aversion to society. A trip to Europe did no good, and while at sea his hands and face would swell and puff up.

I may say also that he was of English birth, and these symptoms came on soon after coming to this country. At one time he had married, and had lost his wife. He formed the habit of masturbating at the age of fifteen, and maintained it regularly for three years to very unusual excess, sometimes committing the act two or three times in quick succession within the space of an hour. At one period, also, he had been excessive with women. For two years had observed a decline in his powers; in dalliance there was prostatic discharge. He was unable to urinate when any one was looking on or waiting for his turn. This last summer the patient had for the first time a full and protracted attack of hay fever in the later or autumnal form.

With all this collection of nervous symptoms there was no evidence, on a single examination, of the existence of spermatorrhœa.

CASE XX.—A gentleman, thirty years of age, anemic as well as neurasthenic, reported that he had suffered for some years from fear of drunken men.* On the horse-cars and in the streets he was in fear of meeting intoxicated persons. The basis of this fear appeared to be the possibility of a row caused by a drunken man. On seeing a person drunk on the ferry-boat, he would go to the extreme end of the boat to avoid him. When a drunken man got on the horse-car where he was, he would at once step off. He dreaded, at certain times of the day, especially when he was exhausted, to go through certain streets, where he was especially liable to meet intoxicated persons. As I have elsewhere stated, these morbid fears are always associated with other symptoms. In this case there were symptoms of excessive itching in the axillæ and on the scrotum; fibrillary contractions; great coldness of the hands and feet; mental depression was also a prominent symptom. He had much muscular vigor, and could walk for miles.

The patient was quite anæmic. As happens with many of these cases, the nerves concerned in the process of erection are abnormally sensitive; crossing the legs and swinging them, or simply riding on the cars, quickly bringing on erections.

Once a month or so, in passing water, he experiences pleasure, as in the emission of semen. There was frequent aching of the limbs, of which such pa-

* These morbid fears seem to be capable of an infinite variety of phases. In addition to the cases that I have already reported in the paper "Morbid Fear as a Symptom of Nervous Disease" (*Hospital Gazette*, July 19, 1879), and to which I may be allowed to refer, I have seen lately a phase of this symptom, the chief peculiarity of which was *inability to go out in the day-time*. He could go anywhere after dark, but was afraid of the light; and all the day was shut up in his house. He first came to see me in the evening.

In this case, as in similar cases, there were no delusions or hallucinations. He soon recovered of this symptom.

tients so often complain, and to which Erb refers in his essay on Neurasthenia.

Urinary analysis in this case found no spermatozoa, very little oxalate of lime or urates, but considerable mucus with pus-cells from the upper portion of the urethra.

Such cases show that there is no constant relation between the nervous symptoms and the ingredients of the urine, at least so far as can be determined by a single examination. The above case advertised his anæmia and neurasthenia in his countenance and bearing and was in reality a severe sufferer, being, indeed, worse than some cases that bore demonstrable evidence of the existence of spermatozoa in the urine.

True and False Hypochondriasis.—Few terms are so often misused in medicine as hypochondriasis. It is applied to almost any symptom complained of by a patient, and doubted or misunderstood by the physician. It certainly would not be improper to call for a definition of this over-used term.

Hypochondriasis, strictly analyzed, is *groundless fear of disease*; and when the word is used by physicians it is to convey that idea that the disease of which the patient complains does not exist in his case, and that his fear that it does exist, or that it may exist, has no foundation outside of his own fancy.

Thus analyzed, hypochondriasis is really one of the many phases of morbid fear, and, like other morbid fears, is a symptom of nervous disease, but not a disease itself, although for convenience' sake we call it such. This is true hypochondriasis or pathophobia, a term justifiable and necessary, and well applicable to many cases; but it is a *relatively far less frequent than is supposed*.

The term is constantly and roughly applied to cases of real, positive, and demonstrable disease, especially functional nervous disease—a sort of wastebasket into which we throw every case that is not described in the books. Symptoms that our senses cannot appreciate, that cannot be seen or heard or touched, and for the existence of which we depend either on the patient's statements or on examinations of the urethra or of the urine, that are not usually made, are referred to hypochondriasis.

CASE XXXI.—A young man, twenty-three years of age, began the habit at the age of seventeen, but had never been remarkably excessive. The chief symptoms at the time when he first consulted me were palpitation and morbid fear, aversion to society. On examination the prepuce was found to be elongated, and the lips of the meatus were red and swollen, as is so often observed in disorders of the prostatic urethra. The patient was in other respects well, very strong and muscular, capable of hard and long work at his trade, which was that of an engraver. The functions of sleep and digestion also were normal.

In this case two facts were clear and demonstrable:

I.—That he feared disease more than he experienced it. He stated to me in deep earnestness that until he saw me he had supposed that he was the worst case in the world, and it was hard for him to believe me when I assured him that his was really one of the mildest cases that I had seen for a long time. This, however, was not true, but false hypochondriasis.

II.—The case is a sample of many persons who are not well, who are truly sufferers from demonstrable though little understood nervous disease, but who, through ignorance purely, add to their real disease a hypochondriasis which is removed at once as soon as they obtain correct information. Such patients are in the condition of a man who has fallen and in-

jured an arm, but fears that a fracture has occurred, until the surgeon appears and makes a clear diagnosis of simple sprain. In strictness this is not hypochondriasis at all. It is the just and inevitable apprehension of ignorance—an intellectual rather than an emotional trouble—and is removed by appealing to the intellect, that is, by informing the patient as to the facts. True hypochondriasis, on the other hand, pathophobia (fear of disease), like morbid fear of all kinds, cannot be removed by instructing the patient in the matter. He knows as well as we that his fear is baseless, and he desires to get rid of it, but is powerless to do so until his exhausted nervous system, of which the morbid fear is a sign and symptom, is calmed and strengthened. Real hypochondriasis, or morbid fear of disease, is rarely or never cured by simply giving the patient authoritative information that there is no ground for his fear. The experiment has been tried for ages by the ablest physicians of the world, and it never succeeds and never can succeed. A genuine hypochondriac may cross the continent and all the oceans to consult some famed physician, so great is his confidence in him; but when, on obtaining the interview, he is told that the disease from which he supposes himself to be a victim does not exist in his case, his morbid fear remains unchanged, he is still pathophobic, and very likely goes around consulting physician after physician.

The two phases, intellectual and emotional fear of disease, may coexist, one form passing into the other. The not being able to rightly diagnose intellectual fear from emotional fear of disease is the basis of much unfortunate advice given by good physicians to sufferers of this class.

In the above case there was real objective disease at the basis of the intellectual fear of disease. There was local irritation in the prostatic urethra, induced by his evil habit, and revealed by examination and indicated by symptoms.

In the majority of cases of so-called hypochondriasis there is some real and demonstrable disease at the basis of the mental trouble, and which can always be found if we but look closely and examine into the condition of every part and organ; the term hypochondriasis being quite often a cover for our lack of thoroughness in examination. Very rarely indeed do I see a case of morbid fear of disease where the urine, or the liver, or the stomach, or the prostatic urethra are in health. In some instances, no doubt, the demonstrable physical disease may be, in part, the result of the mental disease, mind acting injuriously on body and exciting lesions that can be appreciated by the senses; but in all such cases the physical malady needs and should receive treatment just as if caused in any other way.

This day I am consulted by a physician in regard to a patient of which the following history is given: He is twenty-four years of age; has masturbated by intervals for several years, but not to very great excess. He has had nocturnal emissions for over two years, sometimes several times a night. He has lately fallen in love, and sought medical advice in regard to breaking up his habit, but was repelled by a number of physicians who made light of his history, until he fell into the hands of the gentleman who consulted me about him. His present symptoms are severe insomnia, one or two wet dreams every night, indigestion, extreme nervousness approximating to hysteria, and a demented look.

If this man is not sick, then there is no such state as sickness; if these symptoms are not pathological,

then small-pox is health. If a sufferer with such a history is to be dismissed without either examination or diagnosis, then typhoid fever and broken limbs should be allowed to get well of themselves, or put under so-called "moral treatment." In this case the diagnosis was confirmed by the results of medication. Under a proper use of sedatives, directed not to the mind, but to the body, he soon became better, and was still improving, though not well, when my attention was brought to his case.

CASE XXII.—A young man, twenty-one years old, the son of a physician, began the evil habit when fifteen, kept it up for a year, then stopped suddenly, and in six months came emissions twice weekly.

When he consulted me, he had very many of the diagnostic symptoms of sexual neurasthenia, fear of society, both of men and women, but especially of women; mental depression and tremor of the hands under excitement, and the characteristic atonic voice. His muscular strength was unaffected; he could walk ten miles with ease. The irritability of the genital organs was extreme. At one time he would have emissions even while sitting up, if lascivious thoughts occurred; the weeping penis was noticeable. At one stage of his malady he had had emissions as often as ten or twelve nights in succession.

There is in the above history nothing peculiar or anomalous; it is the history of thousands; but it is instructive and worthy of consideration because it is typical. When a physician has in his own family a case of this kind, and sees him from day to day, and finds himself powerless to help or even relieve; when he sees the symptoms that he has been taught to believe are purely subjective—of the fancy only—growing worse and worse, unfitting the sufferer for life duties, he begins to inquire what can be done; and if he looks closely into the facts, he will find that there is a substratum of reality beneath all these symptoms which cannot be blown away by a word, or dissipated by "moral treatment." If the case were an ordinary patient, he could simply dismiss him as a hypochondriac, tell him, as the books require, that nothing is the matter with him, that he is well enough if he will but think so, and the patient goes his way, and he sees no more of him. He may suppose that his advice has done good, that it has been followed; but if he should keep track of that patient, he would see him passing from his office to the office of some professional brother, and so on, and so on, until he falls, by a force as inevitable as gravity, into the hands of the charlatans, who usually go to the other extreme, and tell the sufferer that unless he takes their advice, he will be dead in six months.

In one's own family, or in one's own person, responsibility cannot be shirked in this way; the evil is ever present with us, and forces us to give it attention. A physician whose son has been under my care for sexual neurasthenia, tells me that he has himself been constantly depressed by seeing the depression of his son without being able to relieve it. In this case the diagnosis of hypochondria had been made again and again; but when his urine was examined by Dr. Mitendorf, it was found to contain spermatozoa to the amount of 20,000 in a specimen of a few ounces, and portions of the urethra were as sensitive as a bare nerve. There was also a redundant prepuce. If all this is hypochondria, then death is hypochondria.

Take the following case, also the son of a most intelligent physician:

CASE XXIII.—The patient was seventeen years of age, and had been attending school, and the im-

portant question which I was to decide was, whether he should go on with his studies or suspend them.

The boy began masturbating at the age of fifteen, but had never, according to his own statement, been very excessive. When he first came to my office he burst into tears, and cried almost like an hysterical woman. He had palmar hyperidrosis and some fear of society; there was likewise chronic injection of the conjunctiva. On examining into his case I gave positive advice that he should go back to his school, meanwhile taking general and local treatment. The results have confirmed the soundness of this advice. He began to improve from the first visit, and resumed his studies with zest. In the space of a month, more had been accomplished, keeping him at work and giving him advice and treatment, than in many months of a long vacation that he had occupied in rowing, riding, walking, and various out-door exercises.

In such cases the mind is acted upon, whatever treatment we use. This cannot be avoided, nor is it desirable to avoid it; but the mental therapeutics is not necessarily the only or even the chief element in the cure, any more than it is in any other disease. Indeed, judging from my own experience and experiments, it would seem that *almost all forms of functional nervous disease are more amenable to mental influence than these cases of sexual exhaustion.* No class of patients that consult us are in greater need of definite and well-directed medical treatment than these, and no class of diseases of the nervous system respond better to such measures. These cases are mostly relievable and curable, but, to accomplish relief and cure, we need positive, objective, and, in some instances, powerful treatment.

POISONING BY INOCULATION FROM AN ANIMAL.

By C. H. HUNT, M.D.,

STANWOOD, IOWA.

THE history of this case is as follows: Mr. R—; occupation, farmer; aged forty years; dark hair and complexion; tall, heavy-set; bilious temperament, temperate habits, and enjoying good health; while engaged in killing a hog, cut the third finger of the right hand, on the second joint, on the side next the little finger. The cut was one-half inch in length, and about one-sixteenth of an inch in depth. This occurred about three o'clock in the afternoon. As the wound did not bleed, no attention was paid to it at the time. The next day, about the same hour that the cut was made, while the patient was husking corn, the finger began to be painful; in a few minutes a heavy chill followed, the head began to ache, and he grew so weak that he was obliged to sit down on the ground. It was with difficulty that he reached the house. I saw the patient at seven in the evening. Found him sitting near a hot fire, covered with blankets, and shivering with cold, which, he said, had been pretty severe since five o'clock. The finger was swollen and painful, the lymphatic vessels could be traced from the finger to the shoulder, presenting red and inflamed lines; the axillary glands were swollen and very tender. There was headache, pain in the stomach and back; no vomiting had occurred; pulse 120, and presenting the same feeling as it does during an ague chill. Temperature was not taken. Gave him two ounces of whiskey, in which was dissolved one-half grain of morphine. In fifteen min-

ntes the whiskey was repeated, and he was put to bed. This procedure was a source of much distress to him, as the least movement would cause the muscles of the whole body to ache, as if he had taken an overdose of strychnine. In half an hour the patient began to grow warmer, and his skin was becoming moist. The whiskey and one-fourth of a grain of morphine was repeated, making six ounces of whiskey and three-fourths of a grain of morphine in one-half hour. The patient feeling somewhat better, I left him, ordering two ounces of whiskey every two hours and one-quarter grain of morphine every three hours.

The morning found him better. During the night he had had a severe cramp of the stomach, which lasted about fifteen minutes. He had also taken two grains of morphine, but had not slept any. The morphine was dropped now, but the whiskey was kept up during the day and then discontinued, and nothing was given except some pills to correct the condition of the bowels.

To all appearances the animal killed was healthy, and none of those who partook of it as food suffered in any way.

The symptoms produced by this wound was like those produced by dissecting wounds; but why the flesh of a healthy hog should cause such a difficulty puzzles me somewhat; perhaps some one can enlighten me.

The *modus operandi* of alcohol upon animal poisons must be in one of two ways, as has been stated by others. Either the alcohol destroys the active principle of the poison by contact, or it places the system in such a condition that the poison has no action upon it; probably the former is true. Morphine undoubtedly acts in the same way, as may be witnessed in the treatment of certain diseases caused by septic poisoning.

THE ILLUMINATION OF CAVITIES BY GEISSLER'S TUBES.

By HORATIO R. BIGELOW, M.D.,

WASHINGTON, D. C.

THE stratification of the electric light, by passing a discharge of the Ruhmkorff coil through glass tubes containing a highly rarefied vapor or gas, has been very satisfactorily investigated by Masson, Grove, Cassiot, Plucker, etc. The tubes made by Geissler, of Bonn, are filled with different gases or vapors, and exhausted so that the pressure does not exceed half a millimetre. At the ends of the tubes are two platinum wires soldered into the glass. The stric given by hydrogen under half a millimetre of pressure are white in the bulbs and red in the capillary parts. The stric in carbonic acid under a quarter millimetre of pressure are greenish. In nitrogen the light is orange-yellow. According to Ganot, "Plucker has found that the light in Geissler's tubes does not depend on the substance of the electrodes, but simply on the nature of the gas or vapor in the tube. He has found that the lights furnished by hydrogen, nitrogen, carbonic oxide, etc., give different spectra when they are decomposed by a prism. The discharge of the coil which passes through a highly rarefied gas would not pass through a perfect vacuum, and the presence of a ponderable substance is absolutely necessary for the passage of electricity. By the aid of a powerful magnet Plucker tried the action of magnetism on the electric discharge in a Geissler's tube, as Davy had done with the ordinary voltaic arc,

and obtained many curious results. He found, where the discharge is perpendicular to the line of the poles, it is separated into two distinct parts, which can be referred to the different action exerted by the electro-magnet in the two extra currents produced in the discharge." It remained for De la Rive to prove, in a most ingenious manner, that magnets act on the light in Geissler's tubes in accordance with the laws with which they act on any other movable conductor. As the intensity of the light does not depend upon the number of elements used, it is best to use a discontinuous current with a single element. With the aid of a duck-bill fenestrated speculum, wherein the blades are of the lightest possible construction, very gratifying results may be obtained in the illumination of the vagina. Two bulbs armed with platinum wires are soldered to a capillary tube; this tube is bent in the middle so that its branches may touch, and at its extremity is twisted upon itself. It is then filled with a rarefied gas, and when the discharge passes through, a very brilliant light appears at the twisted end of the tube. In its use there is no inconvenience to the physician and no discomfort to the patient. Abnormal conditions of the external os, and even those derangements which are due to intra-uterine disorder, may be clearly made out. With a sufficiently long capillary tube, the entire cavity of the womb may be brilliantly illuminated.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

WAS IT A CASE OF PULMONARY PHTHISIS?

THE following case was exceedingly interesting as illustrating the difficulty and importance of correct diagnosis:

A female patient, eighteen years of age, said that she was ordinarily well, though not very strong, up to four months ago, when she "was taken with a fever." The fever first appeared towards evening, was preceded by a "chilly and cold sensation," and after it had continued for a short time she began to sweat nights—usually about midnight—and also in the daytime, if she went to sleep. These symptoms continued for about three weeks, when she began to cough. The cough was hacking in character, and continued two or three months before she began to "spit up anything." In the meantime she lost flesh and strength. Last week, for the first time, she spat up a small quantity of dark-colored blood. It was then her time to be unwell, but the menstrual flow did not appear. At that time she had nose-bleed. Since she has been sick her menses have been irregular.

The three prominent points in this history are the following:

1. The patient has had a fever during the past four months, which was preceded by chills, and followed by sweating in the night at about twelve o'clock. With this fever there has been considerable loss of flesh and strength.
2. Soon after the fever began she commenced to have a dry, hacking cough, and her menses became irregular.
3. She went on in this manner until last week,

when she spat up a small quantity of dark-colored blood, and at the same time had epistaxis. She had had pain in the left side that had been increased upon taking a long breath.

Physical Examination.—Her hands were cold, her skin was getting yellow, the pulse was increased in frequency, and her temperature was a little less than 100° F. The temperature in this case was regarded as a very important element—one that would decide important questions relating to prognosis. There was some sweating at night, and it must be decided whether the fever from which she had suffered during the past three or four months, and from which she was then suffering, was malarial in character, or whether it was hectic. If it was merely malarial the sweating was due to depreciation of the vital forces, and had a much less grave significance than when it appeared as one of the factors of true hectic.

But it was said neither the presence of pus nor breaking down of lung-tissue are necessary in order to have hectic fever: for hectic is one of the early and prominent symptoms of tuberculosis. It appears before any local signs of pulmonary phthisis are obtained, when tubercle is its cause. If, however, the temperature of an individual is taken, who has sweating at night dependent upon tuberculosis, it will be found that it is elevated *during the day*. He has fever either in the fore part or in the after part of the day, and when he comes to the night, whether sleeping or waking and coughing, he will have profuse perspiration.

On percussion there was slight loss of pulmonary resonance upon the left as compared with the right side, under the clavicle.

On auscultation there was found, anteriorly, upon the left side, prolonged expiration, a wavy inspiration, but no râles; and there was no bronchial character to the respiration. On auscultation posteriorly, a few râles underneath the scapula were heard, but evidence to much extent of pulmonary consolidation was not obtained—the only evidence being prolonged expiration, and, in her case, it was that that was due partly to obstruction in the bronchial tubes and partly to some change in the lung-tissue itself.

The slightly prolonged expiration and the slight dulness upon the left side of the chest lead to the suspicion of the existence of some localized point of lung consolidation. The evidence, however, was only slight, and was questionable. It was thought that the other physical signs simply indicated a localized bronchitis which interfered with the entrance of air into the lung-tissue. The wavy character of the breathing disappeared when the patient took a full inspiration. There was a loud blowing murmur at the base of the heart, and it extended into the carotids.

On auscultation at the lower portion of the chest, evidences of pleurisy upon the left side were found; that is, distinct friction-sounds were heard at the end of inspiration.

The patient had no hereditary tendency to lung disease. She had but little vitality; had become pale from the examination, and almost passed into syncope. She presented herself with a temperature of less than 100° F., but the probabilities were that it rose as high as 100° F. at some time during the twenty-four hours. The fever at first appeared every other day, but during the last week its presence had been recognized every day. The physical signs are scarcely indicative of more than simple bronchitis with slight pleurisy upon one side.

The fever at the same time did not seem to be

that constant fever which is the accompaniment of phthisis.

It was doubted whether one who had had phthisis for three months could present himself with a temperature no higher than 100 or 101° F.

It was believed that the present condition of the patient led away from tubercular phthisis. The countenance was more like that of a chlorotic girl than of a patient suffering from phthisis.

The fact that the blood which she raised was of a dark color, not bright red and frothy, was expected at the time for the occurrence of the menstrual flow, and was accompanied by epistaxis, it was said, lead away from a diagnosis of phthisis.

Again, the physical signs were not sufficient for pulmonary phthisis. The important point to be determined was whether or not there was dulness upon the left side. There was a difference in percussion note upon the left side when compared with that obtained upon the right, but whether the deviation in pitch was due to pleurisy affecting the lower portion of the left lung, thus intensifying the resonance over the upper portion of the lung, or whether it was due to increased respiration in the right lung, was the question to be decided.

There were no evidences of catarrhal phthisis.

The case was treated on the basis that it was not one of phthisis.

Although the patient was in a condition which might lead to its development, she was treated in accordance with the view that there had been introduced into her system some poison, perhaps septic in character, which had given rise to an irregular form of fever. For it quinine was recommended, and she also received some preparation of iron.

The hygienic management of the case was regarded as exceedingly important.

EARLY SYMPTOMS OF PULMONARY PHTHISIS.

Age: Occurs most frequently between twenty and thirty years of age. *Cough:* Hacking, with little or no expectoration. *Cough:* Continuing for several years without being accompanied by a morbid aspect, can, with considerable safety, be set down as against phthisis. *Progressive loss of flesh* is suggestive of phthisis. *Successive pains* in the upper part of the chest and between the shoulders, is significant of phthisis.

Hemoptysis of itself is very significant, but its absence does not exclude phthisis, nor does its occurrence necessarily indicate the presence of that disease. It has a greater significance when it is preceded and succeeded by a cough.

Persistent elevation of temperature, and persistent increased frequency of the pulse.

Physical Signs.—They are such as indicate slight solidification of lung at the apex on either side, and circumscribed bronchitis limited to the neighborhood of the phthisical affection.

1. Dulness upon delicate percussion.
2. Feebleness of respiratory murmur, or slight broncho-vesicular murmur.
3. Increase of vocal fremitus, and increase of bronchial whisper.
4. Accessory signs; subcrepitant râle limited to upper part of chest on one side, and perhaps at the summit of the chest; pleuritic friction-murmur; true crepitant râle limited to the upper part of the chest; gurgling or crackling sounds limited to the upper part of the chest. All these, or any one of them are important in connection with the history and the other signs mentioned.

BISULPHIDE OF CARBON FOR THE PAINS OF LOCOMOTOR ATAXIA.

A male patient, *æt.* 45, began to have symptoms of his present disease about fifteen years ago. He has locomotor ataxia, and has suffered until quite lately from excruciating pains in his limbs. He has no double vision, but has slight nystagmus. There was marked delay in communication of sensation to the brain from the feet, five or six seconds passing after the foot had been pricked before the sensation was experienced. Besides, there was persistent sensation, the pricking being felt for some time after it had been done. There was also inability to locate impressions correctly. He had not had any trouble with his bowels or bladder, and his sexual desire and capacity were unimpaired. There was no tendon reflex.

By the pains he could predict accurately concerning the weather. For the relief of the fulminating pains, he had resorted to the actual cautery, a variety of remedies, among them gelsemium, which relieved him for a time, and hypodermic injections of morphia. The hypodermic injections impaired his nutrition and produced delirium. All remedies used were discontinued, and for them the bisulphide of carbon was substituted, and, applied to the spine, gave, as the patient claimed, complete relief from all pain.

A second case of locomotor ataxia was seen, in which there was delayed sensation, and also delayed reflex absence of tendon reflex; no double vision, no trouble with bladder or bowels, but marked contraction of pupils. The patient was a midwife and the mother of twelve children.

PROFOUND COMA — CYANOSIS — DYSPŒA — PULMONARY ŒDEMA — VENESECTION — PROMPT RELIEF.

A male patient, *æt.* 48, was admitted to the hospital in a comatose condition, and besides was intensely cyanotic and had great dyspœa. According to the history given by his friends, he had an attack of pneumonia about a week before admission, but when admitted the chest was full of fine and large râles, yet gave no evidence of pneumonia. The heart was much enlarged, the pulse was tense, but no cardiac murmurs could be detected, although a very careful examination was made. Death seemed imminent. The house-physician opened a vein in the arm and took *twelve* ounces of blood. The effect was prompt; the dyspœa and cyanosis were at once relieved, and the evidence of pulmonary œdema entirely disappeared within half an hour. The most urgent symptom being relieved, it was found upon further examination that the patient had left hemiplegia. The urine was examined and found to contain albumen in small quantity, granular casts, had a pale color, was acid in reaction, had a specific gravity of 1010, and the quantity passed was large.

There was incontinence of urine and involuntary evacuations from the bowels.

On the day following admission, claterium was administered. After the operation there was a partial disappearance of the coma, but the patient's intellect still remained impaired.

It was believed that the life of the patient was saved by the venesection. The specific gravity of the urine varied between 1010 and 1014.

EMPYEMA WITHOUT MARKED CONSTITUTIONAL DISTURBANCE, AND GIVING RISE TO ONLY MODERATE DYSPŒA.

A case of empyema, occurring in a male patient about twenty-five years of age, presenting interesting

features relating to physical signs and symptomatology. It had the following history: About two years ago he began to cough, spat some blood, had a pain in his side, suffered from night-sweats, but all the acute symptoms passed away within two weeks, and he felt comparatively well. At the end of six months his left side began to swell, and he had moderate dyspœa. He continued in that condition until March last, when he was tapped; fluid was drawn from the pleural cavity, and the tapping has been repeated. At the present time he feels well, has a good appetite, sleeps well, but suffers still from dyspœa, and came for the purpose of finding out whether or not fluid had reaccumulated, and if he could be relieved by an operation. On physical examination, the heart was found displaced to the right so far that the apex was beating under the right instead of the left nipple. There were no cardiac murmurs. On percussion and auscultation it was found that the level of the fluid was about two inches above the angle of the scapula, not sufficient in quantity to account for the displacement of the heart. It was believed that the position of the heart represented a condition in which the chest contained more fluid than at present, and that, while so much displaced, adhesions formed which retained it in its abnormal position. The case was one of well-marked empyema [purulent fluid was withdrawn], yet the patient's general condition was very good, and he complained only of moderate dyspœa. Prognosis was unfavorable. Two plans of treatment were mentioned: *First*, repeated aspiration; *second*, free incision through the chest-wall, and washing out the pleural cavity. In view of the man's good general condition and age, it was advised to first resort to repeated aspiration, and, if marked improvement was not manifested within a few weeks, to make a free incision through the chest-walls with the view of giving him the best chance of recovery.

Progress of Medical Science.

A NEW MODIFICATION OF THE SHOT-BAG FOR COMPRESSING ARTERIES.—Dr. A. F. Sawyer, of San Francisco, describes a modification of the shot-bag, which he considers has certain advantages over the methods of compression in ordinary use. It consists of a strong canvas bag three inches in diameter by two and a half feet long, the lower extremity closed by a hollow caoutchouc ball two and one-half inches in diameter, the bag being capable of containing twenty-five pounds of fine bird-shot. The apparatus is suspended from the ceiling in the usual manner, a strip of soft buckskin being placed over the skin to guard against chafing. In the case in which the apparatus was tested, its pressure was well borne, although digital and various instrumental pressures were impossible. The application was continued for six hours and ten minutes, when all pulsation in the tumor (popliteal aneurism) ceased. The advantages claimed are rapid work, accurate gauging of the force employed, and the comfort with which it is borne by the patient.

CELLULITIS OF THE NECK.—A consideration of the literature of this subject, together with the results of his own experience, lead Mr. R. W. Parker to suggest the following as a suitable classification of this affection: 1. Idiopathic (angina Ludovici); 2. Trau-

matic, occurring after injuries and operations; 3. Extension of contiguous inflammation. The idiopathic form is a dangerous, and, most frequently, a fatal disease, occurring concurrently with other and more common forms of epidemic disease, such as erysipelas, measles, scarlet fever, and "putrid sore throat," yet, in the most marked cases, the tonsils and pharynx are described as having been normal. The treatment should be bold and prompt; free incisions into the indurated cellular tissue, deep enough to open up the various sheaths of the deep cervical fascia, must be carefully made, so as to let out the sanious ichor, and thus prevent its burrowing. Surgeons are well acquainted with the traumatic form of cervical cellulitis which is apt to make its appearance after all kinds of injuries to the neck. In its treatment Mr. Parker has found the greatest benefit from the use of liquor plumbi made into a lotion with milk instead of distilled water. The most common form of the disease is that due to the extension of a contiguous inflammation. In its treatment, the fact must be borne in mind that much of the danger arises from the inflammation being seated beneath the deep cervical fascia, the undermost layer of which is continuous with the pericardium.—*The Lancet*, Oct. 25, 1879.

SOME OF THE SEQUELE OF SUNSTROKE.—Recovery from sunstroke is frequently incomplete, owing to structural changes in the nerve-centres, giving origin to a variety of symptoms indicative of lesions of a grave character. Sir J. Fayrer, F.R.S., considers these sequelle more common and more serious than is ordinarily supposed, and he cites some cases whose histories tend to support his position. The apparent restoration to health so often witnessed after attacks of this nature is, in many cases, neither lasting nor real, as a careful examination of their subsequent histories will abundantly show. Relapse and death may occur, or secondary consequences, the result of tissue-changes, may destroy life or impair health and intellect at a later period. Insanity is one of the gravest and most frequent sequelle of sunstroke. The cases brought forward would seem to show that this is of an acute inflammatory character, attacking the membranes of the brain, and thus the gray matter, so that we find the mental symptoms more clearly defined than the physical. How far an alteration of structure of bony growth may be traced to *coup-de-soleil* is a matter for further consideration; in all the cases the diploë has been found obstructed and the skull-plates thickened, dense, and heavy, with, in two cases, distinct growth of bone; but both these cases are involved in their etiology—in the one case by an early injury, in the other by a decided hereditary taint.—*Brain*, October, 1879.

A PISTOL-BULLET ENCYSTED IN THE BRAIN.—Dr. John E. Gibson, of Nashville, Tenn., reports an autopsy which he made upon a convict who had been shot in the forehead in the year 1874. Cerebral inflammation had set in after the accident, but recovery ensued, and no ill effects, either physical or mental, were observed up to July, 1879, when a short illness of four days terminated in his death. The following is the account of the autopsy:

"Rigor mortis well developed. Removed calvarium in the usual manner. The wound in the os frontis was closed with cartilaginous matter. The membranes of the brain were in a state of extreme congestion. The right anterior lobe was fully one-third smaller than the left. Considerable effusion containing flakes of lymph found upon the surface of the brain. On making a section of the cerebrum,

found a canal running directly through the right anterior lobe, in an antero-posterior direction. The canal was patent throughout, and formed apparently of cicatricial tissue. It stopped about the centre of the right anterior lobe. At its termination was found the bullet, flattened from its contact with the skull. The bullet was enclosed in a sac that seemed to be attached by a pedicle to the upper wall of the canal. The space in which this hanging cyst had play was considerably greater than the diameter of the canal. Two spicula of bone were found just behind the ball, carried there before it. About the centre of the anterior lobe another spiculum, about the size of a ten cent piece, was found."—*Nashville Journal of Medicine and Surgery*, November, 1879.

AUTOMATIC MEDICAL ELECTRICITY.—Dr. Francis Imlach, in the *Practitioner* for October, describes some very ingenious and useful devices for the application of electricity to paralytics. His thesis is this: "Take a hemiplegic patient, and by automatic electric arrangement, make him raise the dragging limb as he walks, and stand as firmly upon it as upon the other; or make a paraplegic patient in whom, for the present, walking is out of the question, rhythmically flex and extend his limbs by alternating electrization of his flexors and extensors—you do more than merely electrize the paralyzed muscles; his expectant attention is directed in turn to each moving limb, and an effort of will is aroused as the oppressive sense of habitual inability is removed." The writer claims to have proved by the use of his apparatus the truth and practical value of these statements. For treating hemiplegias, he uses a faradic battery, electrodes, wires, and an electric sandal. The electrodes consist of flat pieces of thin, flexible metal, quite narrow, and varying from three to five inches long. These can be tied on to any part of the back or extremities; the sandal is made of boxwood and metal, fastened to the naked heel and connected by ordinary insulated wires with the battery and the electrodes. In the case, now, of a left hemiplegic, where it is desired automatically to contract the muscles of the back of the thigh and calf of the leg, the sandal is fastened to the *right* foot. One electrode is then fastened to the back of the thigh, and another to the back of the leg, both being connected by wires with the sandal and the battery. When the patient, in stepping forward, puts his right heel down, connections are made, a current passes between the two electrodes, contraction takes place in the thigh and leg muscles of the left extremity, which is thus raised up. As the patient progresses the right heel is raised, the current broken, and the left extremity falls naturally forward. This process is continued every time the right heel presses the floor, the left leg and thigh being contracted. Of course the patient can walk no farther than the long wires connecting him with the battery allow, and the exercise must thus be taken indoors. By pursuing the practice, however, for fifteen or twenty minutes every day, very rapid progress is made toward recovery of the full power of the muscles.

By changing the electrodes and sandal, any sets of muscles can be made to contract; and by the use of two sandals paraplegics and ataxics can be treated with much, though not equal, benefit.

Dr. Imlach has a number of other arrangements acting on the same automatic principle, by which various other forms of paralyses can be treated. His idea is evidently a good one, and will probably meet with much favor.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

W.M. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 6, 1879.

ASYLUM MANAGEMENT.

To such as are interested in Lunatic asylum reforms, the recent report of the Senate Investigating Committee has a significant interest. It will be remembered that in March last a petition, purporting to be signed by over two hundred citizens, among which were several medical men, was presented to the State Senate, praying for an investigation into the present system of managing the lunatic asylums of the State. This document emanated from and received the endorsement of the New York Neurological Society. The profession, knowing the character of many of the members of this body, had a hope that much good would come of the course taken, and awaited events accordingly. It is true, some of the charges against the asylum superintendents were extravagant; but in the main, the profession were prepared to believe that some of them could be properly substantiated.

The Senate acted promptly, and referred it to a committee to take testimony with the view of suggesting any necessary measures of reform. That committee went at the investigation in a very matter-of-fact way, by summoning the petitioners to testify concerning the faith within them. Here, however, we come to a part of our story which, although amusing to the general public, is hardly creditable to the profession. We learn, in the first place, that many of the petitioners wished to withdraw their names, stating that they signed the document under a misapprehension. Among these petitioners were several medical men. But what appears stranger than all, is the fact that one or two of the gentlemen who were active in circulating the petition and obtaining signatures thereto, declined to appear before the committee and give their testimony. All this was very bad to begin with, and naturally made rather an unfavorable impression upon a Senate committee prepared to investigate what appeared to be grave charges, made by a responsible body of scientific gentlemen.

If the comparatively few who had the moral courage to stand up to the rack, had an equal amount of good and available testimony to offer for their side, the investigation might at least have been creditable to all concerned. As it was, however, the complainants were so much at a loss for available facts, that they seemed more inclined to apologize for the course they had taken, than to make a show of acting on the offensive. The whole affair degenerated into a farce in which the would-be reformers were the unfortunate actors. The only redeeming feature in the examination was the skill shown by one or two witnesses in making a great deal out of a very little. But this, as far as testimony was concerned, was of itself a confession of weakness. It is true the medical superintendents were out in full force, and volunteered the cross-examination; but the petitioners should have been forewarned of this, and should have been prepared to fight even against such odds. Well-substantiated facts could not be overthrown by any purely political influence which the superintendents might have brought to bear, nor by any well-balanced argument of the accomplished Commissioner of Lunacy. The Legislative Committee did not show any disposition to suppress facts which might be presented, but evidently tried its best to obtain them from the gentlemen who were willing to testify. As far as the printed testimony shows, the complainants had no facts of real importance; at least, if they had, they did not offer them in their examination.

In view of the opportunities which they might have seized of showing up asylum abuses, and of demonstrating the necessities for reform, the petitioners lost an opportunity of creating a proper public sentiment. For this failure they are accountable to the profession they assumed to represent. More than this, they have aroused on the part of the public a spirit of actual antagonism against any demands for reform in asylum management which will take a long time to overcome. Our legislators can desire no better excuse for lending a deaf ear to the entreaties of petitioners than is afforded by the results of the investigation of the Senate Committee and of the comments thereon, which have been made by the secular press.

The published report of the Committee is quite voluminous. On this account we abstain from reproducing it in full, being content with such a general commentary of its contents as will explain the reasons for the following conclusions of the Senate Committee:

First.—The petition is not substantiated in its allegations by any existing state of facts. The Governor, in his last message to the legislature, has spoken of the satisfactory condition of the State asylums from personal visitation.

Second.—The Board of State Charities, an official visiting body, has never suggested any such defects

or maladministration of any kind, in their annual reports to the Legislature. A special committee of that Board (President M. B. Anderson, of the Rochester University, and E. W. Foster), after examining the State asylums with reference to similar insinuations and allegations, reported on December 15, 1877, that "the community is justified in having entire confidence in the administration of these institutions."

Third.—It appears from the archives of the State Commissioner in Lunacy, as well as from his personal statement before the committee, that since the creation of this office no formal complaints have at any time been made or filed with him against the management or internal administration of any State asylum; and his reports and personal statements before the committee show that no occasions calling for special criticism upon such management or administration have, up to this time, presented themselves.

Fourth.—The insinuation of the petition that the superintendents of these State asylums are not thoroughly trained and thoroughly competent medical men, is too notoriously untrue to require denial.

Fifth.—It is not true, as alleged in the petition, that undergraduates in medicine have been appointed as assistant physicians in State asylums. The charge is a reckless misrepresentation of these officers, and under examination the four persons appearing admitted this. From the statements of the superintendents of asylums, it appeared that in almost every instance assistants have received training in civil or military hospitals, and in other cases an equivalent in medical practice after graduation. Outside of the State asylums it appears that but one undergraduate is employed, and that he obtained his place by examination as to qualifications by the authorized medical examining committee of the institution in which he is employed.

Sixth.—In the judgment of the committee, there is no necessity for investigation or examination into the management of any of the State lunatic asylums. This petition sets forth nothing new or valuable, and all the persons signing it, as far as the committee have been able to ascertain, have no personal knowledge of these institutions, or of the allegations made in the petition, and many of them are so obviously and grossly untrue, that they would seem to be the offspring either of ignorance or malice. In either case they are unworthy of notice.

Seventh.—The assertion that the pathological work done in the asylums is of little account, is sufficiently met by a letter addressed to the committee by Professor John C. Dalton, of New York, who stands in the front rank of his profession as a representative of scientific research, and by the testimony of Dr. Buck-

THE TENEMENT-HOUSE IMPROVEMENTS.

No one can avoid feeling the deepest satisfaction at the results already accomplished in the improvement of the tenement-houses and of their inhabitants. It is only a year ago that the condition of a very large number of these dwellings was utterly disgraceful. One thousand, it is estimated, were not only unfit for habitation, but incapable of being made into proper dwelling-places. Only one-tenth of the tenement-houses were in perfect sanitary condition.

Since the agitation of the matter last spring a number of important measures have been accomplished or put under way. In May the State Legislature passed a law amending the Tenement House Act. By this law no dwelling-house can occupy more than sixty-five per cent. of the lot. The space between floor and ceiling must be at least eight feet; each bed-room must have direct communication with outside air, and every occupant must be allowed six hundred cubic feet of air. Money was also appropriated for a sanitary inspection of the tenement-houses. The passage of this law has had already a remarkably good effect. Builders are putting up better buildings; the sanitary inspection has resulted in securing complete records, with diagrams of the construction and condition of the twenty-one thousand tenement-houses in the city. This is a feat which, so far as we can learn, no other great city has accomplished.

Something has also been done in the way of building new model tenement-houses. Two stock companies have been organized; one has collected subscriptions nearly to the amount of \$300,000; the other has received subscriptions amounting to \$75,000. Each of these companies expects soon to commence the erection of one or more blocks of model tenement-houses. Experiments in Brooklyn have shown that small two- or three-story houses can be put up for \$1,100 a piece. These, at a rental of from \$13 to \$20 per month, could be made to pay good dividends in upper New York. Four of them can be put on a lot of 25 by 100 feet.

It seems, however, that there are more projects for building than actual work, as far as this city is concerned. The land costs too much. It is probable, therefore, that in the improvement of dwellings for our poor, more of the work will have to consist in seeing that future tenement blocks do not violate State and sanitary law; and, further, in seeing that the houses already built are kept clean, and that sanitary instruction is given to the lower classes. This latter cannot be too strongly insisted on. Already much good is noticed by the Health Board inspectors as the result of their visits, advice, and circulars. The plan of buying or leasing old and dirty houses, and putting them under strict sanitary regulations, in the few places where it has been tried, has

worked wonders, not only to the health, but the morals of the population. It seems to be the rule that a community is virtuous and well-behaved in inverse proportion to the amount of dirt that environs its life.

The project of giving sanitary instruction to the poor has met with so much favor that an association is to be organized for the purpose of forwarding this end. Such a society could, undoubtedly, do much good. But it will have also many difficulties to encounter. There is a large proportion of the poor, and especially the foreign poor, who will not be taught cleanliness. They will have to be compelled to it; and such compulsion must come chiefly through the landlords. It is this class, a class representing \$200,000,000 worth of property, who must be appealed to, and who have it in their power to secure the greater benefits to the city. The general public sentiment, and the increased activity of the Health Board will assist toward the desired ends of sanitary instruction and reform; but there is much hard work to be done before the best possible results can be reached.

Reviews and Notices of Books.

THE TREATMENT OF DISEASE BY THE HYPODERMIC METHOD. A Manual of Hypodermic Medication. By ROBERTS BARTHOLOW, M.A., M.D., LL.D., Professor of Materia Medica and General Therapeutics, in the Jefferson Medical College of Philadelphia; author of a Treatise on Materia Medica and Therapeutics, etc. Third Edition. Enlarged. Philadelphia: J. B. Lippincott & Co. 1879. Pp. 249.

The author of this volume is to be congratulated upon the amount of information on hypodermic medication that he has condensed in this book. While almost every practitioner of medicine now carries his hypodermic syringe with him, it is seldom used except for the introduction of the salts of opium, and even those who may desire to make a more general application of this method are prevented from a want of knowledge of the solution to be used, the dose, and physiological effects. To all such, this book will prove of great value. It is divided into two parts, one on "The History, Technology and General Therapeutics of Hypodermic Medication;" the other on Special Therapeutics, and consists of twenty-three chapters on those substances that may be used hypodermically, giving under each drug the solution or solutions that may be used; second, the dose; then the physiological effect, and lastly the "Therapy." In this third edition he has added a chapter on the morphia-habit and its treatment, one on chloroform, chloral hydrate, apomorphia, pilocarpine, duboisia, and aquapuncture. He has omitted to make any mention of the use of whiskey in hypodermic injection, an omission we wonder at, as its use is much more general than many of the substances he had treated of.

Our author enters his protest against allowing patients to use a hypodermic, and considers it one of the most common causes of the opium-habit. The book throughout shows the result of close observation and study, being the record to a great extent of

his own observations on the physiological and therapeutic effects of hypodermic medication. It is a book that will well repay a careful perusal.

GUIDE TO THE EXAMINATION OF URINE, WITH SPECIAL REFERENCE TO THE DISEASES OF THE URINARY APPARATUS. By Prof. K. B. HOFFMAN and Dr. R. ULTZMANN. From the Second Edition, translated and edited by Prof. Forchheimer. Cincinnati: Peter G. Thomson. 1879.

This little book, as the authors state in the preface to the first edition, is intended not for the physiological chemist, but for the student and the busy practitioner, and it is undoubtedly well adapted to supply the needs of both those classes of the profession. The various tests for the urine, and the methods of examination, are described concisely and clearly, so that they can be readily grasped by the mind of the beginner, and at the same time with sufficient exhaustiveness to satisfy the practitioner who wants to refresh his memory concerning them, without too much expenditure of time. The subjects are treated in the usual sequence: first, a brief chapter on the histology of the urinary apparatus, then compact descriptions of the physiological properties and chemical composition of the urine, of the abnormal constituents found in it, and of the methods of qualitative and approximate analyses, and finally two chapters on the diagnostic signs in general and local diseases furnished by the urine. The book seems in all respects to be fully up to the times. The translator has done his work fairly well, but without any attempt at elegance of diction. The one great fault of the book is the insufficient number of the illustrations, which should form a very important part in all treatises on the examination of the urine. We must mention, however, that the few illustrations given were interpolated by the translator, the German editions having contained none at all.

Reports of Societies.

THE NEW YORK ACADEMY OF MEDICINE.

SURGICAL SECTION.

Stated Meeting, Nov. 11, 1879.

DR. LEWIS A. SAYRE, CHAIRMAN, PRO TEM.

The Section was called to order at 8 P.M., and the minutes of the last stated meeting were read by the Secretary, DR. A. B. DE LUZA.

UNUSUAL DEFORMITY OF THE HAND BY CICATRICAL CONTRACTION.

DR. A. C. POST reported a case of unusual deformity of the hand occasioned by cicatrical contraction following a burn. One year after a burn received on the back of the hand, the little finger was found behind the ring-finger, and was held in that position by a dense band which extended across to the index finger. By dividing the band and securing the hand to a splint, he succeeded, in the course of a few weeks, in entirely overcoming the deformity, and in securing nearly full motion.

THE MECHANICAL TREATMENT OF HIP-JOINT DISEASE.

DR. JOS. C. HITCHISON read a brief paper upon the above subject, and presented a patient under treat-

ment according to the plan which he recommended. The apparatus consists of an elevated shoe worn on the sound side, and a pair of crutches. As the patient stands on his crutches, the diseased limb is suspended. The shoe is high enough to prevent the toes of the affected side from touching the ground, and the sole should be covered with leather to avoid noise in walking. [For a complete description of the indications for treatment of hip-joint disease, see MEDICAL RECORD, vol. xv., No. 19.]

The paper being before the Section, discussion was opened by DR. C. FAYETTE TAYLOR, who stated that his experience corroborated, in part, that related by Dr. Hutchison. About fourteen and a half years ago a case of hip-joint disease came from Delaware County to him for treatment, and the circumstances were such that he was unable to treat it except by the method described. He directed the patient to have a sole four inches high put on the shoe worn on the sound side, so that it would be impossible for the toes on the affected side to touch the ground; to walk on crutches as long as she could at a time, and also to try to relax the muscles about the hip as much as possible. One year from that time the patient came to him again, when he found that all the symptoms of hip-joint disease had disappeared, and there was complete motion at the joint. For twelve years he had used the self-supporting joint splint, which protected the joint and kept the leg suspended, and unquestionably part of the benefit derived was on account of the ability of patients to suspend the leg longer than they would otherwise be able to do. Yet there was danger in the method, for the patient, who returned, came with the ligaments of the knee-joint so relaxed by the continuous strain upon them produced by the weight of the leg alone, that she was unable to walk. The same result might occur while using the self-supporting joint splint, unless it was protected.

Dr. Taylor further remarked that he suspected he had made a mistake in diagnosis in the case above mentioned, but about one year ago he had the opportunity to examine the affected limb, and found that the trochanter upon that side was about one inch higher than the other; the knee was yet weak. There was no reason to doubt that the girl suffered formerly from hip-joint disease.

DR. A. B. JUDSON remarked that while Dr. Hutchison did not claim any originality in his method of treating hip-joint disease, because it was founded upon principles which had been recognized for several years, and had been carried into practice by Dr. Thomas, of Liverpool, it was an innovation for which Dr. H. deserved great credit. Of course, he must abide the test of time regarding the efficacy of this simple means of treating a most formidable joint affection.

DR. A. C. POST said that a few weeks ago he saw a patient suffering from morbus coxarius, who was wearing the self-supporting splint, and was entirely free from pain while standing, and the mother stated that extension was made at night, and that the limb was painful when extension was not made.

DR. L. M. YALE remarked that he had been highly interested in the paper, because, if the plan of treatment proposed had a general practical application, it would be of immense assistance to those who were obliged to deal with cases which could not procure desirable apparatus. Further experience was desirable.

DR. V. P. GIBNEY stated that he had had a limited experience in the plan of treatment proposed, not

sufficient, however, to enable him to make a report; yet early cases seemed to be doing very well under its application.

There were many cases of hip-joint disease which recovered without treatment, but in the genuine articular disease, that which produced destruction of the joint and surrounding tissues, he had failed to see any treatment which had an effect to absolutely cure the patient, with motion and the limb restored to the same usefulness it had before being attacked by the disease. Any plan of treatment that promised to bring about that result was a desideratum.

DR. GARRISH asked Dr. Hutchison if he would begin his plan of treatment in the acute stage.

He had under his care a patient who had had hip-joint disease on one side, had been treated and recovered, and now was suffering from the same disease, in its acute stage, upon the opposite side; and he proposed to adopt Dr. H.'s plan, if it was applicable in the acute stage, and compare the results.

DR. HUTCHISON replied that he put his plan of treatment into operation as early as possible. Of course there were cases in which the symptoms were so severe that it became necessary to put the patient in bed, but they were exceptional.

THE CHAIRMAN remarked that it was the constant, persistent, muscular contraction, to keep the joint still, which was one of the great elements in breaking down the nervous system of the patient, and produced constitutional disturbance. Constant muscular contraction kept up constant pressure of the diseased surfaces, one upon the other, absorption occurred, and, when it had extended sufficiently far, the acetabulum was perforated and the head, or rather the upper extremity of the femur, rode through it. It was to overcome the constant and persistent action, on the part of the muscles, that some mechanical apparatus was employed which relieved them, and at the same time simply kept the diseased surfaces from coming in contact with each other. [Extension and counter-extension.] By fulfilling these indications, the exciting cause of the muscular contractions was removed, and with its removal went the tendency to reflex muscular movements, and at the same time more or less motion in the joint was obtained.

With reference to Dr. Thomas's instrument, he thought the inventor had not the slightest idea regarding the pathology or the philosophy of treatment of hip-joint disease; that it was simply abominable, and was not the embodiment of any principle whatever. He suggested that the tendency to pull upon the knee-joint too much could be overcome by applying adhesive plaster.

DR. HUTCHISON regarded Dr. Thomas's instrument as diabolical, and one at the farthest remove from the plan of treatment which had just been described. He agreed with the Chairman that extension should be employed to prevent the head of the bone from going through the acetabulum, but he thought the weight of the leg was sufficient to do so, because it was one-fifth of the entire weight of the body, and, therefore, more than was employed when the patient was put into bed and a weight and pulley attached. He had had several cases in which recovery was so perfect that he did not know, from present examination, which limb was affected.

THE CHAIRMAN remarked he was very glad to learn that Dr. Hutchison had had many cases recover so completely, for he himself had had many such cases, but subsequently the diagnosis had been questioned.

DR. GIBNEY remarked, regarding a suspicion that error in diagnosis had been made, that, on a question

where there was so much at stake, one should be able to give all the symptoms and the dates of examination throughout the entire course of the case, and that could be done only by noting them in full as the different examinations were made. Memory could not be trusted regarding the facts found in the early stage, and all the points bearing upon it. He had found himself in a condition to doubt diagnosis, but by making full notes he had found that he was overwhelmingly in error. He should be glad to see a case of *complete* recovery from hip-joint disease; not primary synovitis of the hip-joint, which would have gotten well without apparatus, but that slow chronic disease which begins and progresses as a primary bone disease, the surrounding tissues becoming involved, secondary synovitis developed. It was in such cases as the latter that he would like to see a cure effected without leaving some marked trace of the affection.

DR. TAYLOR stated that during the last year he had been making diagrams of the whole body of the patient, and he had found that in a great many instances where an ordinary examination would not discover any difference between the two limbs, there had been a little difference in the comparative position occupied by the trochanter upon either side. He thought that answered Dr. Gibney's query precisely, for the reason that in many in which, diagnosis being doubted, there had been found evidence of slight previous bony disease, not recognizable by ordinary methods of examination, but sufficient to confirm the diagnosis as correct.

DR. GIBNEY thought that such diagrams would be found to be unreliable, and must be placed in the large collection of signs that failed in a certain proportion of cases.

The Section then adjourned.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Adjourned Annual Meeting, Nov. 24, 1879.

DR. A. E. M. PURDY, VICE-PRESIDENT, IN THE CHAIR. The Society was called to order at 8 P.M., and, on motion, the minutes of the Annual Meeting, as published, were accepted.

THE SECRETARY read the following communication from Dr. Freeman J. Bunnstead, President:

To the Members of the Medical Society of the County of New York:—In my election as your presiding officer, a year ago, I fully appreciated the honor of the appointment, and hoped that my presidency might redound to the interest and welfare of the Society. Unfortunately, during the past year, a severe accident and many weeks of serious illness have greatly interfered with carrying out my purpose. Under these circumstances I can only crave your kind indulgence. Writing from a sick bed, I am unable at present to say more, and must close with the expression of my best wishes for the Society. Sincerely yours."

THE VICE-PRESIDENT then presented the gold medal to Dr. Samuel Sexton, the successful prize-essayist.

The minutes of the meeting were then read and the Society adjourned.

Stated Meeting, Nov. 24, 1879.

DR. A. E. M. PURDY, PRESIDENT, IN THE CHAIR.

The Society was called to order at 8.10 P.M.

There being no minutes to read, DR. HORACE P.

FARNHAM, Vice-President, was called to the chair, and the President delivered his inaugural address. The following is an abstract:

PRESIDENT'S ADDRESS.

After thanking the Society for the honor it had conferred upon him in electing him as their presiding officer, the President assured the members that he should most cheerfully unite with them in all those measures which tended to advance their common interests and elevate their chosen profession. It should be his endeavor to discharge his official duties without fear or partiality, and while he endeavored to carry out the laws of the State relative to the practice of medicine, he should hope for the Society's hearty support and co-operation.

The President then gave a brief review of the history of the establishment of medical societies in the State of New York. It was not until after the middle of the last century that the first law regulating the practice of physic and surgery in this city was enacted, and not until its very close that the first general regulation of the profession of medicine was adopted. "The organization of the State Medical Society and of its branches in the various counties of the State, a history of the successful efforts to establish order in a profession where all had been confusion, is an example which we will do well to follow, and a record we should strive to sustain unblemished." He then proceeded to present the objects for which the Society was organized: First, and primarily, to regulate the practice of physic and surgery; and second, to contribute to the diffusion of true science, and particularly to the knowledge of the healing art.

It was not intended that the Society should be a purely scientific body, and in the light of that view, the President discussed the objects for which the Society was established under two heads:

1. The regulation; and
2. The improvement of the practice of our profession.

For the attainment of the first he believed the existing laws of this State, the system of ethics, and the edicts of the State Medical Society, contained provisions which, if properly regarded, will, in a measure, lead to the suppression of quackery. On this point extensive quotations were made from the recent report of the Board of Censors, regarding the facility with which unqualified persons may obtain licenses to practice medicine, and how the qualifications at present demanded can be rigidly enforced.

Some physicians, in pursuit of an interest distinct from the honor of the science, had acted with candor—with the instincts and manners of gentlemen, and disdaining artifice, while others, impelled by necessity or by baser motives, had recourse to mean and untrustworthy tricks to raise their importance among the uneducated. Some of these acts are mentioned in the Code of Ethics, and quotations were made from Part VI. of the System of Medical Ethics of the State Society, and at the time of their adoption the provisions appeared to be sufficient to exercise a healthy restraint over those disposed to violate them. But the Society had fallen upon different times, and, in its perplexity, had asked the State Medical Society in 1878 for a definition of what was meant by *public advertising*, but no response was made; consequently the Medical Society of the County is suffering from the effects of a system of rules which, at the least, need revision.

The manner of reaching so-called regular physicians who are not members of the Medical Society of

the County was presented by the President as follows :

The President of the County Society should notify physicians not members of that Society, in accordance with Section 1 of the Medical Act of 1827. If the physician so notified fails to comply with notification he forfeits his license, and Section 3 of Act of — declares that it shall be a misdemeanor to practise without a license, and fixes a penalty for so doing. By the special acts incorporating the several medical colleges, their diplomas are made "licenses." "As a society especially chartered to regulate the practise of physic and surgery, have we done the full measure of our duty? If not let us then awake and make an earnest attempt to expiate our past omissions." The President then made brief allusion to the second object of the Society, and expressed his earnest desire to make the stated meetings of the greatest scientific interest.

DUTIES OF DELEGATIONS AND COMMITTEES.

He then spoke of the duties of delegates and of some of the committees. He believed that the Society could instruct its delegates, and that the resolutions instructing delegates were as binding and compulsory as any other resolutions of the Society.

He also believed that "the Committee on Ethics should take cognizance of all patent and public breaches of medical ethics," whether the same were brought to their notice anonymously or otherwise.

THE PRESIDENT then announced the following standing committees :

Committee on Ethics: Drs. Saml. Sexton, Chairman; J. R. Leaming, Wm. M. Polk, J. S. Bryant, and C. Cleveland.

Committee on Hygiene: Drs. J. C. Peters, Chairman; Chas. C. Lee, E. G. Janeway, C. E. Billington, and A. B. Judson.

Committee on Registration: Drs. H. G. Piffard, Chairman; E. D. Hudson and Laurence Johnson.

Committee on Prize Essays: Drs. Fordyce Barker, Chairman; E. Eliot and Austin Flint.

Auditing Committee: Drs. Wm. M. Chamberlain and E. Eliot.

REPORT OF THE COMITIA MINORA.

THE SECRETARY then read the report of the Comitium Minora.

On motion, the report was divided, and the portion relating to granting certificates of membership was adopted.

The portion relating to a resolution introduced by Dr. Piffard at the Annual Meeting in October, and referred to the Comitium, providing that the Society should not respond to the assessment made by the State Medical Society for the publication of its Scientific Transactions, and laid upon the table by the Comitium Minora, gave rise to discussion, which terminated in the adoption of the following resolution offered by Dr. D. B. St. John Roosa :

Resolved, That the Treasurer be instructed to pay the assessment made by the State Medical Society for the publication of its Transactions for the year 1879.

The paper for the evening was read by DR. WM. T. LUSK, and entitled

THE PROGNOSIS OF THE CÆSAREAN OPERATION.

The paper consisted in a careful and brief résumé of the statistics which have been published regarding Cæsarean section, with especial reference to the time of operating, and the surroundings of the patient.

A very large proportion of the entire number of tabulated cases had been derived from reports of lying-in hospitals, in which the showing for all operations was much less favorable than for the same operations performed in private practice, or under specially favorable hospital accommodations. The success in certain districts by certain operators, should not place the operation under ban because in other places it had not succeeded. Why the operation had so often ended fatally could be explained by the fact that it had been performed and the patient remained in an impaired atmosphere of a maternity hospital—surroundings which would make ovariectomy, with its present success, equally fatal as had been the Cæsarean section. The circumstances under which Michaelis operated were such as to render the chances of success almost none, and yet his statistics had continuously appeared as a comment on the safety of the operation. In private practice, delay in performing the operation until the woman became exhausted, even when decided to resort to it, had materially increased the rate of its mortality.

The conclusion reached by Dr. Lusk was that when the Cæsarean section was performed without delay, before exhaustion manifested itself, and was performed under as favorable circumstances as those at present insisted upon in the operation of ovariectomy, the degree of success obtained by Keyser of 81 per cent., or by Harris of 70 per cent., might be expected and perhaps exceeded.

THE PRESIDENT announced that Dr. John S. Billings, U.S.A., would read a paper at the Stated Meeting for December.

The Society then adjourned.

CHICAGO GYNÆCOLOGICAL SOCIETY.

Meeting of September 26, 1879.

PERIMETRIC INFLAMMATION.

DR. H. P. MERRIMAN read a paper on *Perimetric Inflammation*. By this term he included all the inflammations of both peritoneum and cellular tissue about the uterus. He preferred this name to pelvic abscess, pelvic cellulitis, perimetritis, etc. He differed from Dr. Thomas, who believed there was no chronic peritoneal cellulitis; he thought the chronic inflammation was common. Evidence of this was to be found in tenderness about the uterus on examination, particularly at points of slight induration. Such points of induration and tenderness, as well as malpositions of the uterus from adhesions due to inflammation, were to be found in a large proportion of cases of uterine disease. Perimetric inflammations always involved both the peritoneum and the cellular tissue. The most frequent seat of the beginning of the inflammation was in the cellular tissue, in the folds of the broad ligament, and on the left side it occurred more than twice as frequently as on the right.

He believed, according to the prevalent doctrine, that the inflammation was usually secondary to the same condition existing in the uterus, Fallopian tubes, or ovaries. He repeated, with approbation, Emmet's treatment with rest, hot injections, etc.

DR. NELSON said it was highly important, in treating cases of metritis and endometritis, to make sure no chronic perimetritis existed; for treatment proper for the former might greatly aggravate the latter, if present. He related the case of a pregnant woman where, with varicose veins of the left leg and thigh, there was a varicose state of the vessels of the left side

of the cervix and uterus, while the right side was normal. He thought this gave a hint as to the reason of the chronicity of many cases of uterine inflammation. He thought perimetritic inflammations were generally due to some traumatism, such as falls, lifting heavy weights, or violent coitus, with disproportion between organs.

DR. DE L. MILLER said the numerous terms employed to designate inflammations about the uterus was an over-refinement of medical writers. He did not think acute inflammation was confined to a single structure within the female pelvis. Cold-catchings during menstruation was responsible for many cases of perimetritic inflammation. He strongly condemned the prevalent habit among women of taking cold vaginal injections immediately after coitus. Perimetritis frequently caused symptoms of other affections for which patients were treated, of course uselessly. When the inflammation was near the origin of the sciatic nerve, such symptoms were induced as had led to a course of treatment for sciatica being prescribed.

A measure of treatment he favored was counter-irritation by means of a blister over the hypogastrum; this to be fomented a few hours, and then anointed with a mixture of mercurial ointment, powdered camphor, and powdered opium, in the proportion of four parts of the first, two of the second, and one of the third. Injections of hot water should be used, followed by the introduction of carbolized cotton saturated with glycerine, with opium.

DR. RABER believed that acute perimetritis seldom occurred as a primary affection, but was induced by inflammation of the uterus or ovaries, with the aid of some aggravating circumstance.

In the acute form, leeches, hot fomentations over the hypogastrum, and sitz-baths were to be used for local treatment.

DR. SAWYER thought perimetritic inflammations were frequently due to coitus during or near the menstrual period. This greatly increased the natural congestion at such times. He thought abortions often due to a similar immoderate and improper indulgence.

DR. C. W. EARLE alluded to the use of tents of sponge, laminaria, and elm as frequently producing perimetritis. Metallic dilating instruments might produce the same result. Such measures, he was convinced, should be used with great caution. He related two cases where the perimetritis was undoubtedly produced by the careless use of these instruments.

DR. H. W. JONES said sponge-tents often did produce the disease under discussion. Another cause not previously noted, was the abstraction of heat from the feet of sewing women by the metallic treadles of the machines they used.

CHRIST-DEVELOPMENT AND CONSUMPTION. It is stated that, during the last twenty-five years, not a single singer at St. Petersburg has died of consumption, although this disease has outstripped all others, and now holds the first place among the causes of death at the Russian capital. From this and other facts, Dr. Vasilieff draws an inference in favor of the exercise involved in singing, as a preventive measure against consumption. *The Lancet*, in quoting this conclusion, very properly warns the reader against adopting it too readily. It may either happen that singers are not consumptive, because they can use their throat and chest freely; or that consumptive persons are not singers, because the weakness that precedes disease incapacitates the chest and throat for exertion.

Correspondence.

PATHOGENETIC BACTERIA IN SALT-WATER MARSHES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In studying the infusorial life in sweet- and salt-water bodies, I was soon struck by the almost general absence of bacteria in stagnant water, pools, marshes, etc. Around carcasses of larger animals they are always found in abundance, but they are confined to a limited area around the putrefying substance; they do not spread through the whole body of water. Knowing the widespread occurrence of bacteria in the atmosphere, I was the more astonished, but failed to find an explanation for this apparently paradoxical fact. Meanwhile, observations in the fall of last year gave me a satisfactory solution of the problem. In the beginning of fall, in the months of September and October, infusorial life is the richest and most variable.

Having exposed to the air glass jars containing plants and samples of water from different localities, I soon found certain jars full of wrigglers, the larvæ of mosquitoes (*Culex pipiens*) bouncing with the greatest velocity through the water, which proved to be almost entirely deprived of infusorial life. In the struggle for existence, the wrigglers consume all the weaker micro-organisms, and the only infusoria surviving the struggle are the largest Hypotrichous ciliata, such as *Stylonychia*, *Euplotes*, etc.

Closer observation revealed small brownish lumps of a velvety appearance, deposited on the surface of the water, and containing a large number of mosquito eggs, which after a few days are transformed into larvæ. As mosquitoes breed at an enormous rate, the water is soon swarming with wrigglers. To prevent the destruction of my stock for microscopical examination, I had to cover the jars to exclude mosquitoes.

Septic liquids containing putrid meat and decaying plants, giving off a most terrible stench, were purified after wrigglers developed therein, and feasted upon the myriads of bacteria, flagellata, etc. The liquids became perfectly clear, transparent, and odorless—the bacteria at the same time disappearing entirely. Thus I had found in wrigglers the most important factor for controlling and preventing septic processes. Undoubtedly the wrigglers are substituted in other countries by the larvæ of other insects. The scarcity of bacteria, or septic infusoria in stagnant water is lucidly explained by the abundance of wrigglers—they bearing to each other the relation of cause and effect.

Into the study of the etiology of mycotic diseases enters therefore a new element, viz., the conditions regulating the development of the enemies of pathogenetic infusoria—in particular that of the wrigglers.

The present frequent occurrence of septic infusoria will find an easy explanation in the scarcity of wrigglers, which scarcity was brought on in the following manner. The great and sudden reduction of temperature in the latter part of September caused the destruction of mosquitoes, especially the females. Although the cold days were followed immediately by hot weather, only a few struggling individuals were left behind, the principal stock having been killed. A jar with a lively brood of wrigglers in my possession, dates from the beginning of October.

Later on, mosquitoes ceased to annoy me, and I did not need to protect the jars any longer. This scarcity of wrigglers, combined with an unusual high temperature, so favorable to the development of infusorial life, are sufficient to explain the present frequent occurrence of septic infusoria.

Among the pathogenetic bacteria swarming at present in stagnant waters, I wish to allude in particular to *Spirillum undula*, generally of much rarer occurrence than the other septic bacteria. As well known, Obermeier described in *Ctblt.*, 1873, No. 10, a micro-organism resembling *Spirillum tenue*, possessing the same rapid corkscrew-like movement, and living in the blood of patients suffering from recurrent fever. *Spirillum undula* of comparatively large size is a conspicuous object for microscopical examination, and scarcely fails to be detected if present. The transition from the latent or passive state—which state may be easily procured by exposure to cold—to the active state, is readily observed and produced at will. This interesting phenomenon illustrates fully the appearance and disappearance of certain mycotic diseases, and their dependence upon cosmic agencies.

J. J. FRIEDRICH.

74 ST. MARK'S PLACE, NOV. 19, 1879.

DETERMINATION OF SEX IN UTERO.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Under the above heading there have been several articles in support of Prof. Thury's law. A recent case, which seems to me to be what would probably be styled by its supporters as an exception, is as follows:

Mrs. — had a very free menstrual period, February 3d; was confined November 19th; child male; born 6 A.M.—counting back 280 days, February 12th, or nine days after the period that conception occurred. The mother says that she went a week longer than she had calculated on; hence I consider it safe to reckon back 280 days rather than 273 days. And here let me state that in my experience, when exact dates are known, if the product is a male, birth is usually 280 days from the time of conception, but if a female, usually only 273 days. Yours, etc.,
S.

RHODE ISLAND, NOV. 20, 1879.

CONCERNING SO-CALLED PATENTED MEDICINES.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In his remarks on "Pharmacopœial Remedies," in the *MEDICAL RECORD* of last Saturday, "Pharmacopœia" says: "Among the proprietary, trade-marked, and patented medicines largely used by some even eminent physicians, are: McMunn's Elixir, Chlorodyne, and Winslow's Soothing Syrup." Now I beg leave to ask "Pharmacopœia" to explain what is patented in these preparations? What is the reason he calls them patented, or any one of them? I, for my part, venture to say that there is nothing patented about them nor any one of them. The word *patented* used in common parlance is utterly incorrect, and should not be used carelessly by a writer in the *MEDICAL RECORD*. True, there are legions of worthless and dangerous preparations, both proprietary and trade-marked, and it is decidedly a good idea to expose them in medical journals, and show

physicians what is a preferable prescription to them; but I ask "Pharmacopœia" to name a worthless or dangerous preparation in the market which is *patented*? I do not intend in these lines to break a lance for either proprietary, trade-marked, or patented preparations. I only wish to correct a palpable error in which neither pharmacists nor physicians should fall.

JULIUS FEHR.

HOBOKEN, N. J., NOV. 24, 1879.

CORNEAL ABRASIONS CAUSED BY FINGER-NAIL SCRATCHES—TREATMENT.

TO THE EDITOR OF THE MEDICAL RECORD.

DR. GALEZOWSKI, in his preface to Dr. A. Yvert's late work*—*Wounds of the Eyeball*—refers to certain corneal wounds due to the finger-nails of infants, the wounds being very painful and difficult to heal, lasting for weeks and months. The wounds are generally irregular, with small superficial flaps, which lift at each movement of the eyelids. His treatment is to cut off the small flaps.

A somewhat fuller description than the above may not be out of place. The infants scratch their mothers' eyes, not their own. The appearance of the injured eye is sometimes alarming, lids red and swollen, profuse lachrymation, intolerance of light with severe pain in eyeball, and great injection of conjunctival vessels. It is not difficult to see the corneal lesion. The scratch is generally an irregular furrow with unequal edges. The slightly raised edges are constantly rubbed by the lids at each movement of the eyeball. The constant chafing of the lids causes the pain and prevents healing. As to treatment, Dr. G.'s method is excellent, if the flap is only large enough to cut off; but in every case prompt healing can be secured by keeping the eye at rest by means of a compress bandage. The bandage must be firm enough to prevent the lids moving.

PETER A. CALLAN,
Surgeon New York Eye and Ear Infirmary.

EXPERT TESTIMONY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In the *RECORD* of Nov. 8th I notice a quotation from the *Boston Medical and Surgical Journal* on the deficiencies of medical expert testimony. The deficiencies set forth in the article are: "first, a most conspicuous partisanship, even in questions of purely scientific character, the experts being practically retained on one side or the other, and expected to help that side; second, the employment of pretenders and charlatans; third, the fact that the expert's compensation often depends on the result of the trial; fourth, a lack of integrity on the part of the expert, even when he is a person of ability; finally, although there are experts who are both honest and able, there is no system by which their services can be equally applied, for only the party which has money can secure such persons, and the other side must get what they can."

As a remedy for these deficiencies I submit the following plan for consideration and discussion:

Let each State, by act of legislature, be divided

* *Traité Pratique et Clinique des Blessures de l'Œil*, par A. Yvert, Paris, France.

into districts equal in number and area to the judicial districts in the State. For each district let one or more physicians be appointed as medical experts, the term of office to extend over a certain number of years, say the same number as that of the president-judge of the district to which he is appointed. Before receiving his appointment he should be thoroughly examined by a State board of competent physicians created for the purpose. After passing a satisfactory examination, his name should be submitted to the Governor of the State, in whom should be vested the power of appointing. He should be paid a sufficient salary for his services as expert, either by the State or district in which he holds his office, and should be a resident of that district.

It seems to me an act by the legislature, such as that of which the outlines are here presented, would entirely correct the deficiencies alluded to above. It would remove the partisanship, by placing the expert on an impartial ground as the judge himself; it would be impossible for pretender or charlatan to obtain the position. The expert's compensation would not depend on the result of the trial, and, therefore he would not be tempted, for the sake of gain, to give false testimony; nor is it likely that, from the impartial ground he would occupy, he would lack integrity. Lastly, his services would apply equally to all, rich or poor. As the judge decides legal points, so would the expert decide medical points.

F. P. BALL.

SALONA, Pa., Nov. 13, 1879.

THE USE OF THE PRONOUN "WE."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I crave space to enter a protest against the abuse of your editorial prerogative and of English grammar, perpetrated by not a few of your contributors and correspondents who persist in pronouncing themselves "we" (not collectively, but individually). The use of the plural pronoun in editorial writing is justified by the hypothesis that it expresses the conjoint wisdom of an editorial staff; but why a writer who proclaims his unipersonality by placing his name either at the top of his paper, or at the bottom of his epistle, should describe himself in the plural number, as if he were "two single gentlemen rolled into one"—unless, perhaps, it be on the abstract principle of the sovereignty of each and every American citizen—passeth the comprehension and the patience of Yours, etc.,

Ego.

CRESYLIC ACID IN THE TREATMENT OF WHOOPING-COUGH.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In the last number of the "American Journal of the Medical Sciences" is an article by Prof. J. Lewis Smith, of New York, in which he relates his experience with carbolic acid (used in a steam atomizer) in the treatment of whooping-cough.

Last May it was my privilege to have under my care fifteen cases of pertussis in the "Sheltering Arms Nursery."

For a week the treatment was quinine bromide, but the disease was not arrested.

An apparatus for vaporizing "cresolene" was then employed, and the quinine stopped; almost immediately the paroxysms were relieved.

Unfortunately at that time Prof. Smith had not taught me to record the number of paroxysms, and my notes of the cases are very indefinite. It can only be said that the results were most satisfactory.

My colleague did not use the vaporizer during his service. When I again came on duty, I found two new cases well established, the paroxysms very frequent, and the children much exhausted by their severity and the accompanying vomiting. Several other children were coughing with that quick percussive cough so characteristic of the first stage.

The vaporizers were started, and after forty-eight hours the paroxysms had ceased, no more whooping or vomiting; sleep was obtained.

Though children were admitted to the institution, who had not had the disease, no new cases broke out, and the epidemic was at an end.

The vaporizers were used for a month as a safeguard.

The apparatus is simple, inexpensive, and, I believe, unequalled in the treatment of whooping-cough. It is shown in the cut, and needs no explanation.

A word about "cresolene." It is a product of coal tar.

Its chemical composition is C_8H_8O ; that of phenol being HC_6H_4O . In that it contains an additional hydrocarbon, CH_2 , cresolene is homologous to phenol.

Cresylic acid or cresolene is an oily liquid (boiling-point, 397.1°), corrosive to the skin. Vaporized by this apparatus, it reminds one of carbolic acid.

The vapor is not injurious to healthy persons. It has a beneficial effect in allaying the irritation and desire to cough in bronchitis.

This agent deserves more extended trial. I earnestly recommend it, and shall hope to see results published.

JOHN MERRITT, M.D.

BROOKLYN, N. Y.

ELECTRICITY A PARALYZING AGENT.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In a criticism of a portion of my article under the above heading, in a recent issue of the RECORD, Dr. Wm. B. Nestel, in a subsequent issue, raises an objection to which I desire to reply as briefly and pointedly as possible. It is quite true, as he alleges, that the transmission of a galvanic current along a nerve-trunk renders it more "irritable" to the subsequent influence of an interrupted current, if that current is applied in the catelectrotonic region. But this is only a part of the truth in the matter, as we shall presently see.

This galvanic current is necessarily paralyzing in its action, for the following reasons. Even "very feeble and instantaneous passages of the galvanic current produce electrolytic effects" (Drs. Beard and Rockwell, "Med. and Surg. Elec.," p. 116). These effects are essentially of a decomposing and disorganizing character; and acting on so delicate a structure as nerve-fibre it is impossible to regard the result as other than one of reduced vital activity and dimin-

ished nerve-power. Numerous authentic facts show that electricity is not a substitute for nerve-force. A nerve-trunk is not an originator, but merely a carrier of nerve-force. Electricity applied to a nerve-trunk cannot, therefore, act as a producer of nerve-force, and as it cannot be a substitute for it, and moreover as its action is inimical to the integrity of nerve-tissue, it is impossible to see how it can act as a stimulus, though quite possible to see that it may arrest the transmission of nerve-force from the central ganglia to the periphery.

When, after the application of a galvanic current, an interrupted current is applied to that portion of the nerve in which electrolytic action has been most active, and then produces muscular contraction, which it previously failed to do; and when, in addition to this, it is shown by the physiological experiments of men like Sir Astley Cooper, Drs. Kussman and Jenner, Dr. Brown-Séquard and others, as recounted by Dr. C. B. Radeliffe, F.R.S., that muscular contraction occurs to the best advantage in proportion to the absence of the influence of the nervous centres, the inference is fair, that what these currents have been doing is arresting nerve-force, and that the reason why the weak interrupted current succeeds, where it failed before, is that the galvanic current weakened the power of the nerve, and its remaining nerve-force is more easily overthrown, setting the muscle free.

Your correspondent appears to think that he places me in a dilemma when he points to muscular contraction following the application of the interrupted current to the catelectrotonic portion of the nerve, and its failure to cause contraction when applied to the anelectrotonic portion. If the contraction in one case is a consequence of the paralysis of the nerve, he thinks we "must admit that the absence of contractions is the result of an opposite, *i. e.*, tonic condition of the nerve, although induced by the same current." We do not admit this. We see, in the absence of contraction referred to, simply a failure in the ordinary effects of faradization, and we account for this failure as follows: In accordance with Pfünger's law, while every portion of a nerve in the catelectrotonos state possesses increased irritability, every portion of the nerve in the anelectrotonos state possesses diminished irritability (see Dr. Moritz Meyer, "Elec. in Prac. Med. (Hammond)," p. 55) and this diminished irritability accounts for the diminished effect of the faradization of this portion of the nerve. Here we may remark, parenthetically, that increased or diminished "irritability" essentially means a greater or lesser facility for inducing muscular contraction, and may properly be interpreted as a greater or lesser degree of paralysis, which renders its remaining power more or less easily overthrown.

Drs. Beard and Rockwell state that the phenomena of anelectrotonos and catelectrotonos "may be explained by the purely physical effects of the currents in the tissue." The galvanic, or polarizing current, produces electrolytic action, in which acids accumulate at the positive, and alkalies at the negative pole, and "it is a fact in physiology that acids diminish the irritability of nerves, while alkalies increase it" (Ib., p. 115). The same interrupted current, therefore, which suffices to paralyze the nerve in the catelectrotonos, negative or alkaline region, where nerve vitality is most lowered, fails to paralyze it in the anelectrotonos, positive or acid portion, where the susceptibility of the nerve to external impressions is diminished. There are probably other causes also (for a great deal has yet to be learned on

this subject), and among these it may be mentioned that not only is the irritability of the nerve changed, but its "power to conduct the irritability" is diminished, and though this is true of the vicinity of both electrodes, the decrease extends farther in the anelectrotonos portion (Dr. M. Meyer, *loc. cit.*, p. 57).

In view of these facts, I do not think your correspondent was justified in waving "the paralytic hypothesis" aside, with the assertion that it "scarcely requires any refutation," and that "one experiment with the galvanoscopic frog preparation will prove its absurdity." He seems to have overlooked the fact, that what he regards as a difficulty for us is equally a difficulty for him; and if he is not satisfied with our response, we will thank him to explain, in turn, the situation he presents on the theory of the day; and show how electrical stimulation of the nerve-trunk can take place at all; and if it can, how it is that stimulation of the nerve in the catelectrotonos region produces muscular contraction, while stimulation of the anelectrotonos portion fails to do so, as he himself asserts. If electricity be a stimulus and produces certain effects in one case, why not in the other?

We may remind him further that the history of medicine exhibits a series of reversals of opinion—that electro-physiology can hardly be expected to be exceptional in this respect, and that until Prof. Trowbridge's conclusions, evidently based upon careful experiments, are refuted or explained away, very grave doubts must of necessity attach to the previous results of the experiments of M. Du Bois-Reymond and others as regards inherent currents of electricity in nerve and muscle.

There may, of course, be a difference of opinion as to who are "recognized authorities" in electro-physiology, but if your correspondent denies this position to the leading American, British, and German authors whom we quoted, others will hardly coincide with his opinion in this respect.

Should Mr. Neftel favor us with a rejoinder, we trust he will not fail to notice other points in our article, which we need not specify, but in regard to which he will confer a favor by reconciling them with the action of electricity as a stimulant. In conclusion, we ask, why should a chemical agent applied to nerve-fibrils be regarded as a source of nerve-power? May not the tissue-change, besides the disturbance they occasion in the nerve-molecules, more reasonably be regarded as a paralyzing than as a stimulating influence? The same stimulating effect is commonly attributed to a pinch, burn, or shock from other causes. We are, of course, unable to *prove* that these are paralyzing actions, just as Mr. N. is unable to prove that they are stimulating in their character. The opinion to be formed of them is mainly one of inference. But considering the delicate mechanism of nerve-tissue, and its almost infinitesimal associations with the nucleoli of the nuclei of muscular fibre-cells, it seems a rude and unwarranted idea to assume that such assaults on such a structure *eroke nerve-force from nerve-trunks which, after all, are mere carriers and not originators of nerve-force.*

Yours, etc.,

THOMAS W. POOLE, M.D.

LINDSAY, ONT., CANADA, Nov. 20, 1879.

POPULARIZING SANITATION.—Professor Chandler delivered a popular lecture on Public Health, at Cooper Institute, Nov. 25th. He had a large and interested audience.

New Instruments.

A TRIAL CASE FOR TESTING THE VISION.

INTENDED FOR THE GENERAL PRACTITIONER.

This trial case was designed by Drs. D. B. St. John Roosa and Edward T. Ely, especially to meet the demand of physicians in general practice, to enable them to test the vision of any patient, to make a careful diagnosis of some of the more common optical defects so often met with, and give them the power to shield their patients, to a degree, from the baleful influences of the ordinary country vender of spectacles.

It will be particularly useful to the family physician in the examination of patients, who, without external evidence of disease, still complain of their eyes, and enable him to put them upon the road to proper treatment. It is the duty of every physician to urge upon his patients the proper care of their eyes, and thus to do his share toward mitigating a large amount of suffering and loss of usefulness due to neglect.

Specially important is it, that the vision of young children in families and schools should be tested in reference to myopia. If an early diagnosis of this defect can be made, and the subject brought under proper treatment, progressive short-sightedness and all its attendant miseries can be largely prevented.

It is confidently believed that this case will, in the majority of instances, meet all the necessary requirements.

FIG. 1.

Figure 1 shows complete case.

It contains thirty-six pairs spherical trial glasses, convex and concave (eighteen pairs each); they are numbered from 5 to 60, which is nearly as large a range as is to be found in much more expensive cases.

A frame for holding the trial glasses, in which the glasses are held firmly while in use, but can be easily changed, enabling the examiner to make any desired combination.

There is also a set of Jaeger's test-types for near and distant vision, and some general directions for use.

Figure 2 shows frame with glasses in place.

Messrs. Meyrowitz Brothers, of this city, have carried out the wishes of Drs. Roosa and Ely in regard to this case. And, although the case is not intended to take the place of any now used by specialists, it is

FIG. 2.

thought suitable for fulfilling the purposes already indicated, and that a more ambitious plan would render it less generally useful. It is offered to the profession at a price so low as to be within the reach of all.

Obituary.

FREEMAN J. BUMSTEAD, M.D., LL.D.,

NEW YORK.

DR. FREEMAN J. BUMSTEAD died at his residence in this city, November 28th, after a protracted illness. He was born in Boston April 21, 1826. His mother was a sister of N. P. Willis, and he was educated in the High and Latin schools of his native city, and in 1843 entered Williams College and was graduated among the first in his class. Immediately upon leaving college he began the study of medicine, attending lectures at the Tremont Medical School. In 1849 he entered the medical department of Harvard University, going abroad, however, the following year and spending his time in the hospitals of London and Paris. Upon returning to America in the autumn, he was appointed House-Surgeon to the Massachusetts General Hospital, and in 1851 received his degree of Doctor of Medicine from Harvard. In 1852 Dr. Bumstead settled in New York and began the general practice of medicine. In 1853 he was appointed surgeon to the Northwestern Dispensary, which position he filled for two years. He was appointed to the staff of surgeons to the New York Eye and Ear Infirmary, remaining connected with that institution and St. Luke's Hospital for a number of years.

From 1868 to 1871 Dr. Bumstead was Professor in the College of Physicians and Surgeons, resigning in 1871 to go abroad with his family, where he spent two years in extensive travel, visiting the hospitals and medical schools in Great Britain and Continental Europe. During the last years of his life he was engaged, in connection with Dr. R. W. Taylor, in revising and enlarging his treatise on venereal diseases, and making it worthy of its high reputation as a leading text-book. He completed this work, revising the last of the proof-sheets since the beginning of his last illness. Last summer Williams College conferred upon him the degree of LL.D. At the time of his death he was the President of the New York County Medical Society and a member of the New York Academy of Medicine. In 1861 Dr. Bumstead married Miss Mary Josephine White,

daughter of Ferdinand E. White, of Boston, by whom he had four children. These survive him.

His funeral, which was attended by members of the New York Academy of Medicine and the Medical Society of the County of New York, was held at St. Ignatius's Church on Tuesday last. The interment took place in Mount Auburn Cemetery, near Boston.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 23d to November 29th, 1879.

KEENEY, C. C., Lieut.-Col. and Surgeon. Relieved from duty at the Presidio of San Francisco, and assigned to duty in San Francisco, Cal. S. O. 142, Div. of the Pacific and Dept. of California, Nov. 15, 1879.

KIMBALL, J. P., Capt. and Asst. Surgeon. To return with the command of Colonel Merritt, 5th Cavalry, to Rawlins, Wyoming Ter. S. O. 107, Dept. of the Platte, Nov. 20, 1879.

HALL, J. D., Capt. and Asst. Surgeon. His sick leave, granted him from headquarters, Dept. of Texas, extended one month on surgeon's certificate of disability, with permission to leave the Dept. of Texas. S. O. 66, A. G. O., Nov. 25, 1879.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 29, 1879.

Week Ending	Typhoid Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Nov. 22, 1879...	0	15	42	2	84	29	0	0
Nov. 29, 1879...	0	14	43	2	102	51	0	0

HONORS TO DR. FERGUS.—At a recent meeting in Glasgow, a number of citizens presented Dr. A. Fergus with a portrait of himself and a service of plate. The Lord Provost, in making the accompanying address, alluded to the thirty years of long and honorable work through which Dr. Fergus had passed, and also to the recent misfortune by which he had lost a large part of his fortune, through the failure of the Glasgow Bank.

BRITISH ARMY MEDICAL SCHOOL.—This army medical school opened its session November 1st. It had postponed its usual time of meeting one month in hopes that the long-desired army warrant granting proper privileges and emoluments to army medical men would be issued by the government. This was not done, however, and there were, in consequence, no candidates for the army medical department at the school. There were seventeen candidates for the Indian Medical Service, and five for the Royal Navy.

A NEW REMEDY FOR HAY-FEVER. Dr. C. M. Sebastian, of Martin, Texas, reports the case of a patient

who, for twenty-one years, had suffered every spring from hay-fever in a very aggravated form. He had been treated, as a rule, with Dover's powder, extract of hyoseyamus, and the inhalation of the fumes of burning turpentine. Nothing, however, had given him any great relief. At the suggestion of Dr. S., he put on a thick veil when the next spring came and the flowers began to bloom. This gave him rapid and permanent relief. He has now worn the veil for three seasons, and has had no further recurrence of the attacks.—*Medical Herald.*

ASPARAGUS.—Either the shoots or the root of this plant may be used in the form of tincture or syrup. According to Dr. Mary J. Matlack, in the *Medical and Surgical Reporter*, it acts as heart-sedative, and, to a greater extent, as a diuretic. Combined with bromide of potassium, it is very useful in hypertrophy of the heart and in congestive headaches. As a diuretic, it is useful in dropsy and in lithiasis. It seems likely that, as a sedative, it may deserve a place among standard remedies.

DECREASE IN DISPENSARY ATTENDANCE.—The number of patients treated at dispensaries during the past year has been considerably less than in 1878. It is estimated that there have been from 8,000 to 10,000 fewer applicants for relief, including all the dispensaries.

The increased healthiness of the city has been the chief factor in bringing this about. The pay-system, introduced in some institutions, has also reduced the numbers slightly.

CLINICAL STUDY OF CONTAGIOUS PLEURO-PNEUMONIA.—On Nov. 25th, the Professors of the New York College of Veterinary Surgeons, American Veterinary College, and Columbia Veterinary College, held a clinic and post-mortem upon six cases of contagious pleuro-pneumonia. These represented all the cases in the city. About one hundred veterinary students were present; also several physicians.

The animals were subjected to a physical examination and the signs noted. They were then slaughtered and examined. Marbleizations and pleuritic adhesions were found in each case; in one case a large abscess existed.

It was stated that there have been only a few sporadic cases in the city during the past summer, and no danger from an epidemic is to be apprehended.

LUNACY REFORM.—A meeting was held on the 23d ult. to consider the subject of securing reform in the care of the insane. The Rev. Dr. Bellows presided, and a number of prominent physicians and humanitarians were present. A paper was read by Miss Chevalier presenting the subject, and relating the history of the late successful improvement to secure similar reform in Massachusetts. In this Miss Chevalier had taken a prominent part. After some discussion a committee, consisting of Mr. L. S. Metcalf, Dr. Mary Putnam-Jacobi, Miss Collins, Dr. C. L. Dana, and Col. Robert Hoe, were appointed to make arrangements for a public meeting to be held December 18th. At this meeting a number of prominent men will speak, including Mr. G. W. Curtis, Dr. E. C. Seguin, Dr. Chapin, of the Willard Insane Asylum, Rev. Dr. Bellows, Dr. Willard Parker, Jackson S. Schultz and Rev. Dr. Storrs. It will be the object of the meeting to present to the public the deficiencies in the present insane asylum management, to organize an association for the protection of the insane, and to appoint a committee which will endeavor to get some legislative action in behalf of reform.

Original Lectures.

PSORIASIS.

IS IT A LOCAL OR CONSTITUTIONAL DISEASE?

A CLINICAL LECTURE DELIVERED AT THE WOMAN'S
MEDICAL COLLEGE, CHICAGO.

By WM. J. MAYNARD, M.D.,

PROFESSOR OF DERMATOLOGY, WOMAN'S HOSPITAL MEDICAL COL-
LEGE, AND PHYSICIAN TO SKIN DEPARTMENT, CENTRAL
FREE DISPENSARY.

(Reported for THE MEDICAL RECORD.)

I wish to-day to invite your attention to a cutaneous disease known as psoriasis, and in so doing it pleases me to state that we have in the patient before us a perfect type of this affection, with its different phases of eruption. It is not necessary, perhaps, that I should enter into a very extended description of this disease, for, however vividly this might be portrayed, it would be but trivial in comparison to this ocular demonstration. In this connection, however, there are a few practical points that I would like to have you retain in memory, for they will greatly assist you in the future, when, as practitioners, you will be called upon to diagnosticate this affection to the exclusion of others somewhat similar. First, then, let me call your attention to the fact that we have here beautifully shown the manner in which the eruption will assume differences as to shape and sizes of the patches, and to these have been given certain names which indicate the form without signifying any change in the character of the anatomical lesions. Thus, that you may not in any way be misled by these long euphonious terms, I will explain that the disease always commences by small reddish spots that are immediately covered over by whitish scales; that these spots, because they are distinct and somewhat resemble a drop of mortar, are called psoriasis guttata. Here you will notice that they are somewhat larger, and as they are quite round, distinct, and the size of a coin, are called psoriasis nummularis. Here we find that, by spreading out irregularly, or from a coalition of several of these spots, there is a more extended or diffused form of the eruption. This is popularly termed psoriasis diffusa, and is often seen upon the elbows and knees when not so apparent on other parts of the body. Thus you will notice that these names are but mere outlines of the same disease, and should not in the least be confusing to you. You will observe, also, that most of these patches are quite covered with whitish or pearly scales, and by scraping them with my knife you see that they are quite easily detached, and there is exposed to your view a bright red or hyperæmic base upon which a number of minute bleeding points have sprung up. Now, this is so characteristic of this disease that you can always rely upon it as an aid in diagnosis when you may be in doubt. You will notice, again, that the eruption on this individual is the best defined or more diffused on the extensor surface of the limbs. This is what is usually witnessed, and I have seen a number of cases where the elbows and knees were the only parts of the body attacked. I wish also to say in this connection, that the eruption in psoriasis is always dry, and has not at any time in its history a stage of exudation, as is so often seen in eczema. There is more or less itching attending this eruption, but it is at times so slight as not to cause

any discomfort to the individual. Psoriasis is a well-marked disease, and, as a rule, easily recognized, because it possesses certain peculiarities that are quite characteristic. Occasionally, however, you will meet with cases that bear a very close resemblance to it, and to these I must call your attention for a short time. Sometimes these round patches in the later stage of the disease will clear up in the centre and leave a perfectly distinct ring that may closely resemble tinea circinata or ringworm. In tinea, however, the scales are not so thick and bulky as in psoriasis, but rather more branny and of a grayish color. In ringworm there is no tendency toward symmetry in the development of the eruption, but it will attack any portion of the body, and then, too, we most always have a history of contagion. In very doubtful cases, the microscope will lend us very material assistance, for all cases of tinea depend upon a vegetable parasite whose mycelium and spores can be generally seen, while no such thing ever exists in psoriasis.

Sometimes upon the link will be found chronic patches of eczema that very closely resemble patches of the eruption under consideration; but when arranged side by side, we will be told that the itching of these patches of eczema is much more intense and constant; that in a majority of cases there has at some time been some exudation; that the scales are much more firm and more tenacious; that the borders of these patches are not so well defined as in psoriasis, but have a tendency to shade away into the surrounding healthy skin. Occasionally we meet with cases of syphilitic psoriasis that so closely resemble the non-specific form that great care and experience is necessary to establish the differential diagnosis—a matter of very great importance, since it renders another course of treatment absolutely imperative. In a majority of such cases you will be able, with a little tact, to receive some evidence of antecedent contagion. If this, however, is not possible to obtain, either through concealment or from the fact that the earlier lesions have been passed by unnoticed, then you must rely upon the appearance of the existing eruptions. Thus, in syphilitic psoriasis these spots are not a bright inflammatory red, as we see here, but rather of a dark red or purplish color, and are only partially covered over with thin, branny scales, which, on account of their tendency to rapidly exfoliate, leave this base quite exposed. In this variety the extensor surfaces, as the elbows and knees, are not necessarily affected, but the eruption will occur upon any portion of the body without regard to symmetry in development.

Patches of psoriasis that exist solely upon the palms of the hands, without being seen upon any other parts of the body, are, according to my experience, invariably syphilitic. Usually, when speaking of the treatment of skin diseases, I have always remarked that the first thing for you to do is to find out what is the matter—to always search for some hidden cause that, in a majority of instances, lies at the foundation of the difficulty. But, in the disease under discussion, I am not able to point out any such cause to you. In a record of 1,500 consecutive cases of skin diseases, I find that psoriasis has occurred eighty-four times, and yet, in a large majority of these, there has really been nothing the matter, as far as I have been able to ascertain. These cases have been very carefully examined, and their organs have been pronounced sound in functional activity. There are many authorities who strongly insist upon certain diatheses, as the strumous, dartrous and gonty,

and who see in these all that they desire for the establishment of this affection. Others have soared in neurotic enthusiasm over perverted innervation, and have seen in their fancy, excesses at the table, both in eating and drinking, mental emotions, too abundant use of azotized food, coffee, etc., raise the mischief with a patient's cutaneous cells, all through the influence of the trophic nerves. It is a good thing to be a good theorist; there is a great deal of satisfaction in it, for we can tell exactly in our own mind how our medicines are going to act on the most complex organisms, as well as explain the cause of different pathological lesions. But these theories, my friends, do not amount to very much unless they can be substantiated by absolute facts and experience. I am inclined myself to grow enthusiastic on the etiology of disease, and you know how often, when speaking of the management of these cutaneous disorders, I have directed my treatment toward the correction of certain internal disorders that appeared to possess modifying, if not causative influences. In psoriasis, however, I am not able to find these hidden causes that are claimed and insisted upon by other observers. How many times have I examined the urine of these patients in the hope that some changes here might account for this disease, or at least establish the presence of lithæmia or the gouty state, which is, undoubtedly, a strong factor in the product of eczema. I have pushed my examinations farther, and have made particular inquiries in reference to good or faulty assimilation, knowing full well how often the organs of secretion and excretion are concerned in other affections of the skin. I have searched for hereditary influences, particularly in reference to scrofula and phthisis, and yet these records show a good family history, provided the statements made can be relied upon.

A few of these have shown an occasional attack of bronchitis and rheumatism, but they have been in so small a minority that I have no reason to suspect that they were any way associated with or concerned in the etiology of the disease. For these reasons, then, I am of the opinion that to a certain extent the skin possesses a sufficient amount of inherent independence to carry on special pathological changes, without the coexistence of other functional disturbances, that there are also many diseases of the skin that are essentially local in their nature and are cured by local treatment. In this class I would place psoriasis, regarding it as a simple hyperæmia of certain portions of the skin, including the upper layers of the corium and accompanied by a manifest proliferation of dried epithelial cells. If these statements are correct, and I have every reason to believe in their truthfulness, you will probably agree with me that there is no particular necessity for internal medication. There really is no particular demand for this, for the disease can in many cases be cured by local treatment alone; and yet I prescribe arsenic very frequently in psoriasis, and have a good deal of confidence in it, for it forms a capital adjunct to my external remedies. Then, too, it pleases the patient more to take something internally, for nearly all afflicted with this disease firmly believe that their blood is out of order, and nothing that you may say or do will convince them to the contrary. It is thought by many of the profession that arsenic is a sovereign remedy for about all the ills that the skin is afflicted with; but this, I can answer you, is a very great error, and one that will lead to bad practice, for there are really but very few cutaneous diseases

where we can expect great benefit from this drug. In advising the use of arsenic, then, I do not give it to these patients in the belief that it will effect such an alteration in the blood that its influence will soon be felt in favorable tissue-changes, or that a clue to its action will be found in the regions of nervous pathology; but rather its action is as a simple tonic to the system, and during its elimination through the skin it plays the part of a cutaneous irritant, and by this means stimulates the process of repair. That it is such a stimulant to the rete, that it even acts as an irritant to these cutaneous cells, is well shown, I think, from the fact that, when used in acute psoriasis and in other forms of skin disease of an acute character, they are invariably made worse by it, while the more sluggish and indolent the disease the more rapid will be the improvement. If then this is the true action of arsenic in psoriasis, you can readily understand how it becomes at once an auxiliary to our local treatment, for this is generally stimulating, and why it is so often prescribed and held in such high esteem by practitioners. When prescribing this potent remedy, then, you should always commence with a small dose, generally three to four minims of Fowler's solution properly diluted with water. You should also give this with perfect regularity three times a day, and always after meals, for it is very liable to irritate the membrane of the stomach if given while fasting. It is rarely necessary to increase this dose, for you will remember that it must be taken perhaps for months, and even this amount is liable to produce unpleasant symptoms, as swelling and itching of the eyelids, pain in the head, gastric disturbance, etc. These unpleasant effects should always be borne in mind, and should be the signal for further reduction of the dose, and, if necessary, its entire suspension. Arsenic is a perfectly safe remedy, and may be given for months without any bad results, provided you are cautious and keep your patient under surveillance. Let us now turn our attention carefully to the local treatment, for here also you must use some caution, both as to a choice of remedies and your manner of using them. First, then, examine into the true condition of the eruption. If you find its development of a very recent date, and running an acute course with inflammatory symptoms, here most assuredly you must use soothing applications, for your patient would not be able to endure the stimulating treatment that I am about to recommend. In these cases also there will be a constant exfoliation of scales, which must be removed first by plain or alkaline baths. A very good one for this purpose may be made by dissolving a pound each of borax and bicarbonate of soda in thirty gallons of water. After this bath the patient should be anointed with cosmoline or vaseline, and this treatment continued until the eruption fades away or becomes sufficiently chronic to allow a more stimulating application.

We have in the patient before us a very good example of this chronic condition, and, as she has had the disease for some time, her skin will, I think, bear this stimulating treatment very well. These scales should be removed in the manner I have just described, but unfortunately she belongs to a class that do not indulge very much in the luxury of a bathtub, and so we must content ourselves with repeated washings of soft-soap and water. This will remove the scales sufficiently, and then she should be rubbed with an ointment containing fifteen grains of chrysophanic acid to the ounce of lard, or cosmoline. I have been using this drug for the last two years, and like

its action very much; at least, it seems to remove the disease much quicker than other remedies applied for the same purpose. It, however, should be used with great care and should be applied only to the patches of the eruption, for occasionally we meet with patients who cannot tolerate the drug, on account of its extreme irritating effect upon the skin, producing either a diffused redness around the whitened patches, or an inflammation that extends over a larger surface and is accompanied by some febrile symptoms. If you are careful, however, to use it only in the more chronic cases, these disturbances will not often occur. Another objection to its use is the peculiar staining of the skin left after the application, which to some is exceedingly disagreeable, and on this account it has been my custom to use the acid on the parts covered by the clothes, and substituting for the face and hands the *sapo viridis*, or what is generally known as German green soap. This may be used alone, or, if found too irritating, with one or two parts of alcohol. Pyrogallie acid has of late been mentioned as a substitute for chrysophanic acid, when this cannot be tolerated. It is claimed that its action is quite similar, but much slower and milder. As it does not dye the hair nor produce any inflammation of the skin, it can be used much more freely upon all parts of the body. This acid is soluble in water and should be used in a ten per cent. solution.

I have not as yet had sufficient experience in the employment of the drug to speak in positive terms of its asserted efficacy. The tarry preparations, *pix. liquidæ* or *oleum cadini*, may also be used with good results, either in ointment with lard or cosmoline; or, if these are objectionable as lotions, with alcohol or cologne spirits. With these remedies at your command you will be successful, in a majority of instances, in removing the disease. Occasionally, however, you will find it exceedingly obstinate, and even when apparently cured will relapse without the slightest provocation, especially in the winter season. In these particular cases I would advise you to continue the arsenic treatment for several months after the subsidence of the eruption, in the expectation that it will act favorably toward preventing its reappearance. From these personal investigations, then, I am led to the belief that psoriasis in a majority of instances is purely a local disease; that it is often removed by local means alone; that arsenic is curative only as it acts in conjunction with the local treatment. I am a warm advocate of the influence of functional disturbances in their relation to skin diseases, and with my statistics taken entirely from that particular strata of society called upper crust, my views may be somewhat changed on this subject, for I am always ready at any time to be governed by a preponderance of truth. I am confident, however, that this will not occur, for I have already seen a sufficient number of cases in private practice to thoroughly substantiate these views, gleaned mostly from dispensary experience. While claiming the local origin of psoriasis, it is but just to say to you that my opinions are not in accordance with those of many dermatologists, and that a majority perhaps will favor its constitutional origin. Still, these deductions are the results of my own experience; and verified as they are by other good observers, I give them to you in the hope that your own future investigations will corroborate them.

KENTUCKY SCHOOL OF MEDICINE.—Dr. M. Kampf has been appointed Professor of Surgery in this school.

AMNESIC APHASIA AND AGRAPHIA.

RIGHT-SIDED HEMIPLEGIA DEPENDENT UPON THE FORMATION OF A CLOT IN BROCA'S CENTRE OF SPEECH, WITH SUBSEQUENT SOFTENING.

A CLINICAL LECTURE DELIVERED AT THE PENNSYLVANIA HOSPITAL.

By J. M. DA COSTA, M.D.,

PROFESSOR OF MEDICINE AND OF CLINICAL MEDICINE IN JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

(Reported for THE MEDICAL RECORD.)

THIS man presents a very peculiar form of cerebral disease as a result of apoplexy.

H. L.—, *æt.* 40, Irish by birth, and a tavern-keeper by occupation. He presumably shares in the habits of men of this persuasion, and has, in fact, told us that he has been formerly of very intemperate habits—in other words, an habitual drunkard.

During the past five years he has been subject to peculiar attacks, in which he has become suddenly unconscious, and has remained so for several minutes at a time. He stated, or rather his friends told us when they brought him here, that he had never had convulsions, or exhibited convulsive movements, and had never frothed at his mouth. Thirteen days prior to his admission, which was on the 27th of October last (1879), while apparently in good health, he fell to the floor unconscious and remained so for some ten minutes. When he regained consciousness he was entirely unable to speak. His wife says that the right arm and leg were paralyzed, but that this condition subsequently improved. When the man was admitted to the wards we noticed considerable muscular rigidity in the right arm and leg. He moved his right leg as if it were an artificial member, bringing his heel down stiffly, with the toes extended. The arm could also be moved voluntarily, but it remained in any position in which we chose to fix it for several minutes, just like an automaton. The grip of the right hand was impaired—was, in fact, quite feeble.

As regards the patient's sensation, we found that it was markedly impaired all over the body, the right side a little more so, perhaps, than the left. You may say that this statement must be received with some doubt; that we have to depend entirely, as regards the question of sensibility, upon the patient's answers, and that the man's condition is not such as to warrant us in placing any great reliance upon facts for whose demonstration his concurrence is necessary. In this you are largely right; still, however, I think you may receive, as a well-proven fact, the statement that the man's sensation is duller on the right than on the left side of his body.

During all this time he has not spoken. You notice that the expression of his face is quite vacant and confused. All the while that I have been telling you the particulars of his case, he has been accompanying my remarks with confirmatory nods, which may not be regarded, perhaps, altogether as signs of an intelligent understanding of what we have been discussing. Still he takes cognizance of the most part of what is going on around him.

To go still farther into the case, there is a very doubtful history of specific disease. Indeed, in summing up all the evidence, I am inclined to think that there has not been any specific disease. Still, I will leave the question open.

The urine has been carefully examined and found

to be acid, pale, cloudy, and with a specific gravity of 1010. At times there was a very small amount of albumen found in the test-glass, but as the most recent analysis has failed to reveal its presence, we must conclude that albuminuria was but a temporary phenomenon.

The electro-muscular contractility of the right side of the body is impaired. It moves, but not so freely as the left side of the body. The faradic current, however, elicits a ready response.

I am going to ask him some questions :

"Have you had your breakfast?"

"Yes."

"Have you had your dinner?"

"Yes."

"Have you had your supper?"

"Yes."

You see, gentlemen, he answers "yes" to everything. He possesses, in truth, but one word in his vocabulary, and that word is "yes. Once, or twice, I have noticed a faint attempt on his part to answer "no," but the "yes" vastly predominates.

I would call such a case in the abstract, or, to use a better term, generically, a case of *aphasia*. This term we must at present accept as meaning a deprivation of the patient's power of speech, while he still retains the power of understanding what we say, in a certain way, and of moving his lips

"Can you whistle?"

Yes; he can make the effort and put his lips in the proper position. This proves that there is no crippling of the muscles of the mouth or face, and no impairment of the muscles of articulation.

Taking up this clue, then, let us look farther. Let us see if the man understands what I say. In other words, let us try and discover whether the case may not be one of idiocy accompanying the aphasia, whether the patient's brain is not as slow, or slower than his tongue. How are we to proceed in this examination? I hold up my watch before his eyes.

"Is this a fork?"

"Yes."

"Is it a watch?"

He cannot say, and yet when I ask him again :

"Is it a watch?" he nods his head with a gleam of intelligence.

"Is it a penknife?"

"No."

He shakes his head. His intelligence is very evidently impaired, but it is not gone. There is nothing like idiocy. This statement which you may, perhaps, think has not been very decidedly proven by my questions and his wavering answers this morning, has been confirmed by repeated observations made in the wards, which have shown that it is not so much a confusion of his ideas as a lack of keenness and accuracy in the man's grasp of them. He is unable to express himself because he has lost his speech, and not because he is an idiot in any sense of the word.

This point has been further tested in the wards by the use of the battery. It had been thought that it might be an instance of idiocy, consequent upon dementia from alcoholism, where there was a loss of muscular power associated with the dementia—in other words, that it was a case of alcoholic dementia with paralysis. For the purpose of testing these points we applied a strong current to the man's skin by means of the electric brush. Such an application, as you all, no doubt, know, gives rise to great agony, such pain that nobody can hold his or her speech under the use of a strong current; it is the best method in

our hands for detecting malingerers. Yet, although the expression of the patient's face showed that he was suffering great pain, not a single word escaped from his lips except a whispered "yes." We thus established our diagnosis of the existence of actual aphasia.

Let us now, before concluding, go somewhat into the cause of this man's condition, and then let us discuss the indications for the treatment of the case.

I have already called your attention to the doubtful history of syphilis in the case, but have, at the same time, declined to consider that history as authentic. There is no history of malaria and no history of heart-disease; no murmur, no dilatation. The kidneys are in good order. Occasionally there is a little albumen in the urine, but it is a very inconstant phenomenon.

His eyes have been examined with the ophthalmoscope, and the evidence is entirely negative; there is no distinct alteration. This examination has been rendered very much easier by the fact that the man's pupils are constantly dilated.

But let us pursue the subject still farther, and let us see whether he has any means left him of communication with the outer world. Has he lost the power of speech only, or is he also unable to write?

"Take this piece of chalk and write your name on the blackboard."

"Is that your name?"

"Well, now write your age."

Notice that there is no crippling of the hand here, gentlemen; the patient tries his best to write, and this is an additional proof of intelligence on his part, but these two short, uncertain, wavering lines are all that he can give us to express :

"Henry L., et. 40."

Our patient has plainly lost the power of written language—is, in other words, *agraphic*.

But there is yet another point in the case to be tested. I will try and see, although I allow that it is not easy to determine the point in one so deprived of the power of speech—I will try and see whether the man can repeat words after me, and also endeavor to determine whether he still preserves the memory of words, or whether memory, as well as power of expression, has been effaced.

"Say 'clinic;' say 'room.'"

You see that he cannot repeat either of these words after me, although he tries very hard to do so.

The other matter is to see whether he still has an appreciation of words, or whether he has lost his sense of their meaning. This point I have already tested when I showed him my watch and asked him whether it was a watch or a penknife, but I will try it again.

"Is this a piece of soap?"

"Is it a glass of water?"

He nods his head, yes, to both questions. He is not sure about its being a piece of soap. He is evidently fatigued, and so, without examining him any further, you may take my statement, based upon numerous examinations in the wards, that, as far as I can judge, his memory of words is to a large extent lost; so that generally, when I have mentioned a word to him, he has not understood it, but occasionally, after thinking awhile, the word has returned to him. Perhaps I had better modify my statement and say that his memory for words is comparatively, but not altogether lost.

I have, by these examinations, established a number of facts. I have made out a case of aphasia and *agraphia*, with right-sided loss of power. It has also been shown you, I think, that the man's mind is slightly impaired—though the idea is present, the

word is wanting—so that the case is one of amnesic aphasia—loss of words, of the power of writing, to some extent only, of intelligence.

What is the underlying cause of all this? What has been the lesion? Where is the lesion? Any one of you who has paid much attention to the advance of physiological science of late, will know that the centre of speech has been located in the left frontal convolutions, and especially in one of these convolutions—the so-called speech-centre of Broca, named after M. Paul Broca, to whom we owe most of our knowledge of this speech-centre. It has been proved by numberless experiments that a destructive lesion of this portion of the brain deprives one of the power of speech.

This brings us to the consideration of another question: What is the nature of the lesion in the present case? We cannot be quite as certain regarding this point, since any lesion destroying these parts will give rise to the same general symptoms. Still I do not think it beyond the province of diagnosis to settle upon the true nature of the lesion.

You will have noticed that the disease came on suddenly. The acute stage was, it is true, preceded by temporary insensibility upon several occasions, but the attack which brought the man into the hospital was, nevertheless, a very sudden one, and when we come to inquire into the cause of such sudden attacks, we find that they are always the result of an apoplexy. In the present case, then, we would say that there had either been (1) an apoplexy in Broca's speech-centre, or (2) that an embolus had been arrested there, or (3) that there had been a sudden clotting in the vessels of that region—in other words, what might be called a thrombus. This last supposition we can dismiss at once, because the condition is a very rare one, and because, when it does happen, there are always marked convulsive movements present, and the hemiplegia is less marked than we find it to be here.

Which of the other alternatives do I fix upon? I think that we have here an apoplectic clot, caused by the breakage of degenerate, atheromatous vessels. I think that this clot is small, and is limited to the centre of speech. I give this opinion, because (1) of the sudden, marked attack of unconsciousness; (2) by reason of the hemiplegia; and (3) on account of the absence of any symptoms of disease of the heart, which, were they present, would favor the theory of an embolic cause for the attack, just as their absence is a strong argument against it.

Is this all I have to tell you regarding the case? No. The clot has been followed by slow tissue-changes—in other words, by local softening; for, if the formation of the clot had not been followed by such softening, we should not have had the impairment of intelligence noted in this man, nor the persistent loss of the power of articulate speech.

To sum up, then, we have a case of aphasia, in the broad sense of the term, as a result of the formation of a clot in Broca's region of speech—the posterior part of the third frontal convolution on the left side—and the clot has been followed by subsequent softening of the surrounding parts.

Right-sided Hemiplegia.—Let us turn our attention to this symptom of the case. Is right-sided hemiplegia common in cases of lesions involving the left anterior frontal convolution of the brain? It is very common—is, in fact, the rule, and a rule which has but very few exceptions. In this respect, then, the present case has been a typical one.

There has been something very peculiar about the

loss of power in the present case. At first this loss of power was complete, then the paralysis diminished; but, even at this comparatively late period in the attack, the grasp of the man's right hand is very feeble. This paralysis was soon followed by rigidity and spastic contractions of the muscles of the right arm and leg when put into motion. This tendency to rigidity is not so marked in the leg as in the arm. The man can move the fingers of his right hand; but, when I hold the arm out at length and then let go my hold suddenly, instead of falling, the arm stays rigid for some time in the same position, like an automaton's or a cataleptic's arm. I want to call your attention in particular to this point of difference between the hemiplegia in this case and that which usually accompanies this condition. Can we draw any conclusion from this difference? I think we can. When there is any rigidity of the muscles following the hemiplegia consequent upon a clot, it should be regarded as an indication of the existence of a progressive irritative lesion of the brain, showing that the nerve-centres are still in a constant state of irritation.

I hope that I have succeeded in laying before you the many diagnostic points of the case, so that they have possessed their real significance in your eyes.

This brings us to a consideration of the questions of prognosis and treatment.

The patient having been taken out of the room, I may tell you that the prognosis in these cases is bad, if our diagnosis has been correct in regarding the case as one dependent upon the formation of a clot with subsequent softening. Indeed, we cannot hope for any permanent good results from our treatment. I have seen cases recover their speech, but I fear this man never will do so entirely.

His treatment has consisted mainly in the administration of nervous tonics. He has been taking cod-liver oil and iron. At one period in the attack Basham's mixture was given. Something may be accomplished by improving his nutrition; so let us give him the hypophosphites—two drachms of the compound syrup of the hypophosphites and half an ounce of cod-liver oil thrice daily. Let us also use faradization to the affected muscles, and particularly to the muscles of the tongue. This faradization of the tongue is sometimes attempted with great advantage. You will say that such a procedure would be irrational, but it is not nearly so irrational as you would suppose. We may in this manner stimulate, by some obscure connection, the nervous centres themselves.

Numerous attempts have been made to stimulate the central system by applications of the continuous current over the seat of the disease in the brain, but the results thus far have never been as good as those obtained by stimulating locally the muscles of phonation.

I think that this case of cortical apoplexy has been pregnant with clinical features of interest and instruction to us all.

GURUN BALSAM, OR WOOD-OIL.—This balsam is obtained from a tree in India, and is largely used for gonorrhœa by the natives. It is recommended very strongly by M. Vidal as a remedy for obstinate vaginitis. He soaks a tampon of cotton in equal parts of the balsam and warm water, and inserts it in the vagina. It is to be renewed every day.—*Gazette Hebdomad.*

Original Communications.

CEREBRAL "IRRITATION" AS A SOURCE OF MOTOR NERVE-POWER.

BY THOMAS W. POOLE, M.D.,

LINDSAY, CANADA.

"LOOKED at from a purely professional point of view, the simple question for us is: Does irritation of the cortical gray matter on the upper and outer part of the cerebral hemispheres tend to produce convulsions? And this question may now undoubtedly be answered in the affirmative." (Dr. C. H. Bastian: "Paralysis from Brain Disease," p. 76.)

Before this answer is given and accepted, it is of the utmost importance to apprehend the true nature of the "irritation" referred to. The cortical gray matter of the hemispheres is so little susceptible to irritation of any kind that the severest mechanical injury may be inflicted on it, such as cutting, tearing, burning, etc., and that, too, in the perfectly conscious and normal condition of the animal, without evoking any reaction of a muscular or spasmodic kind. Electricity was, till recently, believed to be equally inoperative, since currents, which, if applied to motor nerves, tetanize the muscles, produce no effects when applied to the cortical substance; and it requires currents more powerful than these to produce the desired localized convulsions of corresponding muscles. Under these circumstances, by what right are the cortical motor centres said to suffer "irritation" from any of the causes mentioned above? It is evident that their susceptibility in this respect is altogether exceptional, and that what may be a source of irritation to ordinary vascular tissues is not such to the cortex cerebri. Dr. Ferrier, indeed, denies that cauterization of the cortex cerebri is productive of irritation, and if this be true of so severe an operation, surely we ought also to admit the absence of irritation in other morbid changes—the result of exposure to the air, of lesions gradually forming, of hæmorrhagic clots, or of other processes of a character apparently much less intense.

Dr. Ferrier, however, and physiologists generally, are accustomed to see in the class of cases just mentioned, the presence of "irritation," and it is necessary they should assume it to be present, because the production of spasms and convulsions is theoretically regarded as due to the evoking of increased motor nerve-power from the centres in question, the hypothetical "irritation" furnishing a cause for the production and discharge of the motor stimulus to the muscles, requisite under that theory.

But is it true that "irritation" of nerve-centres necessarily implies *increased functional activity* on their part? We know that in inflammation—the very highest form of irritation—notwithstanding the appearance of increased excitement (which is deceptive), the vital power of the part affected is really depressed (Dr. Carpenter). Again, from the very nature of irritation, it may be held to be closely allied with pain, and "the essence of pain" is "perturbation of nerve-function, a disturbance quite different from mere exaltation of the normal development of nerve-force." "Pain is not a true hyperæsthesia; on the contrary, it involves a lowering of true function" (Dr. Anstie: "Neuralgia," p. 12.) The presumption is that what is here held to be true of

pain is true, also, of "irritation," and that, in one case as in the other, functional power is lowered.

The occurrence of muscular spasm and convulsion as a concomitant of depression or paralysis of the nervous centres is quite in accordance with the results of the physiological experiments of Sir Astley Cooper, Drs. Kussmaul and Tenner, Dr. Brown-Séquard, and others, as recounted by Dr. C. B. Radcliffe, F.R.S. ("Lectures on Epilepsy," etc.), in which it was shown that spasm and convulsion take place in proportion to the *absence* of the ordinary control exercised by the nervous centres over the muscles. It will be seen that, in this view of the case, the "irritation" referred to above in the opening quotation from Dr. Bastian, with its supposed increased functional activity on the part of the nervous centres, is not necessary to the onset of convulsions, which occur to the best advantage when the implied conditions of "irritation" and excess of nerve-power are entirely wanting. This being the case, it is desirable to inquire more particularly whether there is sufficient proof that any such alleged "irritation" is present in these states at all, or whether what has been called "irritation" is not really a condition of depression or arrest of motor nerve-power, a condition which, in the experiments referred to, was shown to be most conducive to spasm and convulsion of muscle.

Now, Dr. Ferrier is a leading authority on this subject, and we propose to examine the chief experiment adduced by him in proof of the "irritation" theory. He writes: "The first experiment I have to record is instructive, as showing the respective effects of irritation and destruction of the convolutions bounding the fissure of Rolando. The right hemisphere of a monkey had been exposed and subjected to experimentation with electrical irritation. The part exposed included the ascending parietal, ascending frontal, and posterior extremities of the frontal convolutions. The animal was allowed to recover, for the purpose of watching the effects of exposure of the brain. Next day the animal was found perfectly well. Towards the close of the day following, on which there were signs of inflammatory irritation and suppuration, it began to suffer from choreic spasms of the left angle of the mouth and left arm, which recurred repeatedly, and rapidly assumed an epileptiform character, affecting the whole of the left side of the body. Next day, left hemiplegia had become established, the angle of the mouth drawn to the right, the left cheek pouch flaccid and distended with food, which had accumulated outside the dental arch, there being almost total paralysis of the left arm and partial paralysis of the left leg. On the day following, the paralysis of motion was complete over the whole of the left side, and continued so till death, nine days subsequently. Tactile sensation, as well as sight, hearing, smell, and taste were retained. On post-mortem examination it was found that the exposed convolutions were completely softened, but, beyond this, the rest of the hemispheres and the basal ganglia were free from organic injury."

Dr. Ferrier adds: "In this, we have a clear case, first, of vital irritation producing precisely the same effects as the electric current, and then destruction by inflammatory softening, resulting in complete paralysis of voluntary motion on the opposite side of the body, without affection of sensation." ("Functions of the Brain," pp. 200-202.)

Here, it will be noted, the spasms of the muscles began to occur contemporaneously with "signs of inflammatory irritation and suppuration." Are these

conditions favorable for increased functional activity? We have already quoted Dr. Carpenter's opinion in the negative to this inquiry. And if inflammation be attended not by exalted, but by depressed vitality, how much more is this true of suppuration, which appears to have shown itself very early in the process? Have we not here rather a failure or arrest of motor nerve-force, producing the very condition which Drs. Kussnaul and Tenner, and the other experimenters mentioned above, found most conducive to the occurrence of muscular spasm and convulsion; the inherent contractile power of the muscles asserting itself when no longer adequately controlled by the restraint of corresponding nervous centres?

As to the subsequent presence of "paralysis" rather than spasm and rigidity, we have to observe:

1. The term "paralysis" is one which should be restricted to the nerve, and is not at all applicable to the muscle, whose power of contraction is not destroyed, but is merely restrained, and survives even the general death of the organism. Thus, Dr. Dickson remarks: "The opinion that a true muscular paralysis exists, is, I believe, an error." ("Med. in Relation to the Mind," p. 265.) If instead of regarding spasm and "paralysis" of muscle as opposite conditions, we interpret them as varying degrees, or stages, of motor nerve paralysis, we shall find in what is called muscular "paralysis," a loss of co-ordinate power and of voluntary control, the nerve still dominating the muscle; whereas, in clonic spasm we have an alternation of the balance of control between the nerve and muscle, and in tonic spasm, or rigidity, a cessation of motor nerve restraint, setting the muscle free to assert its inherent contractile power, and the latter passing into a degree of rigidity proportionate to its freedom. Softening of the brain frequently produces rigidity as well as "paralysis" of muscles, and the occurrence of one or the other may be held to depend on the greater or lesser degree of the paralysis affecting the motor centres.

2. It may be fairly questioned whether softening is a legitimate result of *suppuration*, and it would be interesting to know if, in Dr. Ferrier's case, the microscope was employed as the only certain means of verifying the presence of that state. (Dr. J. H. Bennett.) But there is nothing even in the presence of the softening here reported, incompatible with the view, expressed above, of a modified motor nerve restraint over the muscle in the state of "paralysis." For numerous instances are on record in which softening did not prevent the operation of motor impulse; and, as Dr. Carpenter remarks, "we are still far from having an accurate knowledge of the degree of structural change in the nervous centres incompatible with the continued performance of their function." ("Phys.," p. 669.)

3. Considering that animals sometimes not only survive, but in great part recover from much more severe operations than the one practised in this experiment, there is no certainty that death resulted from the exposure of the surface of the brain; and it is quite probable that other local or general causes, among which imperfect nutrition is likely to have been prominent, induced the fatal result. So far from the brain affection proceeding from bad to worse, the fact of suppuration at the close of the second day, and the absence of pus, sloughing, or waste of tissue, on the post-mortem, on or after the thirteenth day, seems rather to denote an effort of repair and a partial recuperation of function on the part of the cortical motor centres which enabled them to reclaim, in part, the loss of restraint over the muscles, as seen in

the arrest of the spasms and the return to a quiescent state of the muscles, as the result of that restraint, though still powerless to the will.

These considerations serve to account for the phenomena of this case, as depending on differences in degree of an uniform condition of depression or paralysis of function of the cortical motor centres, to the exclusion of "irritation" as a factor in the case at all. And if it be true, as Dr. Ferrier asserts, that the application of a red-hot iron to these same cortical centres is not a source of "irritation," but produces rather paralysis of function, ought not the same doctrine to be applicable to a lesser form of injury, the result of mere exposure, which is surely a much less potent cause of irritation than the actual cautery?

In Dr. Ferrier's second case, "the left hemisphere of a monkey was exposed, and the cortical substance destroyed by the cautery," involving several recognized motor centres of localized muscles. "In this case the paralysis was confined to the same movements as result from electrical stimulation of the centre specified." (Ib., pp. 202-3.)

We have elsewhere collated authentic facts, from leading authorities, which appear to prove that electricity is neither a stimulant nor an irritant, but a paralyzer of nerve-tissue. We believe the facts justify the opinion that by this quality of its action it arrests motor nerve-power, and by so doing brings about the condition (referred to above) most favorable to the occurrence of muscular contraction. In this view of the case what does this experiment teach?

That electrical paralyzation of certain cortical motor centres produces definite localized contractions in muscles associated with these centres; the muscle contracting in proportion to its freedom from nervous restraint, as determined by the intensity of the current and the consequent motor paralysis.

Cauterization of the same motor centres produces a lesser degree of motor paralysis, and with this, less freedom of the muscles, which, while co-ordination is destroyed, are still sufficiently restrained from passing into spasm, and hence manifest that negative position known as "paralysis."

Here, again, no place is found for "irritation." Such a view of the case is, of course, directly antagonistic to the generally received doctrine that in a state of spasm and convulsion the motor centres are excited, and are "discharging" nerve-force with unusual vigor—an excess of function for which the lowered vital power of the afflicted centres appears very unfavorable, and a doctrine of the causation of spasm and convulsion, which the evidence of the able experimenters before mentioned shows to be untenable.

It is worthy of note, in this connection, that the hypothesis of the late Dr. Todd, which ascribed the muscular contractions of "late rigidity" to an "irritative" condition of the circumscribed lesion in the brain, has been definitely discountenanced by such authors as Bouchard, Bastian, Hammond, and others, who find the cause of this rigidity in secondary *degeneration* of the spinal cord; and surely a condition of this kind is not favorable for the generation of an excess of nerve-power in the spinal centres, whereby the muscles are to be stimulated to pass into a state of rigidity.

The contractions of "early rigidity," have not, so far as we can ascertain, been attributed to "irritation" by any one; and if the theory of the day is to be maintained, that such contractions are dependent upon undue activity of the nervous centres, we are

left without any explanation of the rigidity here occurring.

It has, however, been customary for authors to attribute, sometimes an irritating, and at others a paralyzing, effect to congestions, extravasations, or other morbid states of the brain and cord. (Dr. J. H. Bennett's "Clin. Lec.," p. 406; Dr. Brown-Séguard, etc.) Dr. William A. Hammond thus expresses this idea: "The symptoms which follow spinal hemorrhage are the result of excitation and compression, the hyperesthesia and the spasms being due to the former, and the anæsthesia and motor paralysis to the latter." ("Dis. Nerv. Syst.," p. 442.) Now, in cases where the paralysis (from compression) is confined to one limb, or to one set of muscles, and the rigidity (from excitation) to another, this view of the case might seem plausible; but, as usually happens, the paralysis and the contraction of the limbs or muscles go together. We might easily multiply quotations from the leading authors to prove this. Such phrases as, "paralysis ushered in by convulsions," "hemiplegia with spasms," "rigidity of paralyzed limbs," "coma, paralysis, and tonic spasms," "rigidity supervening in the paralyzed side," "unilateral convulsions" with, or following, "unilateral paralysis," "general paralysis with rigidity and contraction," etc., appear on almost every page of chapters devoted to this subject. Can we believe that in such cases the motor nerves, which are paralyzed, are at the same time conveying an excess of energy wherewith to stimulate the muscles to pass into the state of contemporaneous contraction here witnessed?

Dr. W. A. Hammond finds, "very conclusively," in progressive muscular atrophy, that the seat of disease is not primarily in the muscle, but "in that part of the nervous centre from which the nerves come which supply the muscle." "The destructive metamorphosis of the nerve-centre proceeds at a greater rate than its nutrition," and, as a consequence, the nerve suffers exhaustion and atrophy of its cells. (Ib., p. 674.) And yet, in every one of his cases of this disease, Dr. H. finds "fibrillary contractions" of the parietic muscles. What does this prove? That the exhausted and atrophied cells of the nerve-centres were generating and sending an excess of nerve-force to the muscles to induce these contractions? No; but that the deprivation of nerve-force, so natural under the circumstances, had liberated the muscular fibres from their customary nervous restraint, and the inherent contractile power of the fibrille of the muscle asserted itself accordingly, in proportion to their freedom.

Instead of dwelling longer on organic lesions, and the evident failure of nerve-power which they occasion—a subject which might be greatly extended—let us glance, in conclusion, at the nerve-centres in those purely functional disturbances which are also productive of spasm and convulsion.

Dr. C. H. Bastian refers to these states as consisting in "a mere molecular damage of a recoverable kind which must have taken place in the nerve-elements, a damage or derangement which, for a time, hinders their proper life-changes, and so puts a temporary stop to their functional manifestations." We ask the reader to note this language carefully. He continues: "In these cases a large amount of nervous energy is liberated in the cerebral hemispheres, and a rapid down-rush occurs upon the motor ganglia at the base of the brain, as we see by the cries and sudden muscular movements which accompany such states. This sudden down-rush of energy or 'discharge' upon the motor ganglia, induced by emotional causes, while

it often produces chorea, seems occasionally to induce mere loss of speech, or the same temporary paralysis as that which is produced by the nervous discharges of an attack of unilateral epilepsy, which then goes by the name of emotional hemiplegia." ("Paralysis from Brain Disease," p. 27.)

Here, it is asserted, we have "a damage or derangement" of function in the nerve-elements, which "hinders their life-changes" and "puts a temporary stop to their functional manifestations," a condition which surely may well be held to result in deprivation rather than in excess of nerve-power. And yet it is under these avowed conditions of arrest of function that we are told excessive discharges of nervous energy take place from these same centres! And what is the result? "Chorea" (which other authorities assert results from nervous weakness), "loss of speech," and "temporary paralysis." Extraordinary effects, truly, from a "down rush" of "a large amount of nervous energy liberated in the cerebral hemispheres;" but just the effects, naturally, to be anticipated from a deprivation rather than from an excess of nerve-force. This "paralysis" is said to be closely associated with "unilateral epilepsy," another name for a species of hemiplegia. Mark the connection here again between paralysis and spasm or convulsion.

In this remarkable passage, which we have fully quoted, we find a process which begins in damage, derangement, and arrest of function; then presently exhibits a marked excess of functional activity, and speedily results in loss of function in the parts on which it is ultimately expended! Is there here the natural and proper sequence between cause and effect? And if such be really the scientific medical teaching of our time, what opinion will future generations entertain of us and of it?

Is it not fair to conclude that this confusion and contradiction are chargeable to the theory of the day, which requires a stimulus from the nerves as a condition of muscular contraction, and that this stimulus, in the case of spasm and convulsion, is sought to be derived from a hypothetical "irritation" in organic lesions and functional disturbances of the motor centres, in both of which cases motor nerve-power is really depressed, and, as a consequence of that depression, the muscles are proportionately set free to exert their inherent power of contraction?

ULCERATION AND CONTRACTION OF THE RECTUM FOLLOWING SEVERE DYSENTERY—LUMBAR COLOTOMY.

PATIENT PRESENTED TO THE NEW YORK ACADEMY OF MEDICINE, NOVEMBER 20, 1879.

By ALFRED C. POST, M.D., LL.D.

RICHARD CLARK, laborer; born in Ireland; æt. 30; admitted into Presbyterian Hospital, December 22, 1877.

Previous history: In the fall of 1876, while at work making excavations in wet ground, he had an attack of dysentery. In the course of two or three months pus appeared in the stools. Under medical treatment, the stools lost their dysenteric character, but a more or less abundant purulent discharge continued until the time of his admission to the hospital, with rectal tenesmus and severe pains about the anus after each passage. The patient gives a good family history. There have been no syphilitic antecedents.

On admission, the general health of the patient

seemed to be good. A fissure of the anus was found posteriorly, and ulceration of the rectal mucous membrane an inch or more from the sphincter. He has about six passages a day.

December 23d.—Suppositories of compound gall-ointment and iodoform were ordered to be introduced into the rectum daily.

December 30th.—As the fecal matter is hard, and its passage causes severe pain, sulphur sublim. was ordered in $\frac{z}{i}$ doses morning and evening.

January 9, 1878.—The patient was etherized, and the sphincter ani dilated sufficiently to rupture some of its fibres. On examining the rectum with a speculum, no ulceration was brought into view, but there was circumscribed congestion of the mucous membrane, with some ecchymosis just within the verge. Sulphur discontinued to-day.

January 26th.—Patient's condition is somewhat improved. The fluid extract of ergot was ordered in doses of ten minims three times a day.

February 2d.—Injections of carbolic acid, one to thirty, were directed to be given morning and evening.

February 12th.—Patient was etherized, placed in Sims's position, and examined with a speculum, with the aid of a strong light. An annular constriction was found two inches from the anus, extending half way around the gut on its left side. This is probably the cicatrix of a chronic ulcer, of which a part remains unhealed on the posterior wall of the rectum. This spot is very sensitive. Ordered suppositories of iodoform, gr. v., morning and evening. Discontinued carbolic acid injections.

Feb. 26th.—Patient has had but one passage to-day; it was of soft consistence, and without pain. But there was pus with it.

March 24th.—When the stools are hard they give rise to severe pain. The stools are more or less purulent, but not bloody. Bougies have been introduced from time to time. Their introduction at first was quite painful, but it is now much less so.

April 7th.—Ordered injections of arg. nit., gr. ij. in $\frac{z}{i}$ iss. of water.

May 1st.—The strength of the injection was increased to gr. v. of arg. nit., in $\frac{z}{i}$ iss. of water.

May 21st.—The actual cautery was applied over the left iliac region.

May 30th.—Discontinued injections.

July 1st.—Injections of arg. nit., gr. v., were resumed, and were continued until July 24th, when the patient left the hospital in a somewhat improved condition.

On the 27th of January, 1879, he was again admitted to the hospital, and his condition was much less favorable than when he left in July. When he came under my care in February, I found extensive ulceration in the rectum, involving the whole thickness of the mucous membrane and nearly the whole circumference of the intestine, and two or three inches in length. The patient suffered great pain when he had an evacuation, and for some time after. The ulcerated surface was touched with a sol. arg. nit., $\frac{z}{ss}$, to $\frac{z}{i}$, every second day, and care was taken to avoid constipation. But no marked relief followed, and he expressed a strong desire to undergo any operation which would afford a chance of relieving his sufferings. Accordingly, on the 27th of March I performed colotomy in the usual manner, in the left lumbar region. The operation was well borne, and the wound healed kindly. Since that time his evacuations have occurred without pain, through the artificial anus, and the general health of the patient has greatly improved. He wears a compress of oakum

over the artificial anus, kept in place by a bandage around the body.

Nov. 20, 1879.—For several months past bougies have been introduced through the contracted portion of the rectum, beginning with instruments twenty-nine millimetres in circumference, and finally using a bougie fifty-seven millimetres. The instruments have been introduced every second day, and daily injections have been administered of liq. soda chlorin. diluted with eight parts of water. Minute portions of fecal matter have passed through the rectum on one or two occasions; but there have been regular evacuations through the artificial anus, occasioning but little inconvenience to the patient. The artificial anus is on a level with the adjacent integument, there being no prolapsus of the bowel, and no irritation of the skin in the neighborhood. The patient is very well satisfied with his present condition as compared with his state before the operation.

The operation of colotomy for the formation of an artificial anus has usually been resorted to in intestinal obstruction occasioned by malignant disease of the rectum. Its performance in non-malignant ulceration and contraction of the rectum, although not unprecedented, has been very rare. But in cases of great severity and obstinacy, like that which is the subject of the present paper, the operation appears to me to be an eminently proper one, relieving the patient from great suffering, and affording a chance of many years of life and of comfort.

CONGENITAL ABSENCE OF RECTUM.

By ALFRED LUDLOW CARROLL, M.D.,

NEW BRIGHTON, N. Y.

On November 23, 1878, I was called to see a male infant, born four days before, under the ministrations of a midwife, who had finally discovered that there must be "something wrong" about her little charge, as no evacuation of the bowels had taken place, despite her ineffectual efforts to exhibit an enema, and in defiance of sundry doses of oil. The child was much emaciated, with pinched features, cold extremities, tympanitic abdomen, fecal vomiting; in brief, seemingly moribund.

On examination, the anus and external sphincter were normally formed, but on attempting to introduce the finger a cul-de-sac was found, not more than half an inch in depth. The absence of any bulging or sense of fluctuation excluded the idea of a mere membranous septum or brief interruption of the rectum, and the abdominal distention was too great for palpation to afford a distinct clew to the situation of the upper intestinal pouch.

Perforating the anal cul-de-sac with a trocar (5 mm. diameter), I cautiously felt my way, keeping at first in the mesial line, and well back toward the concavity of the sacrum, and deflecting the instrument somewhat to the left after reaching the level of the sacral promontory. In the earlier part of the procedure the sensation was as of penetrating an unyielding, dense tissue; at the height of about two and a half inches this feeling of resistance diminished; but it was not until the entire length of the trocar ($\frac{3}{4}$ inches) had passed that the cavity of the bowel was reached, a large amount of flatus and some fecal matter following the withdrawal of the trocar. The depth of the wound forbade any attempt to bring the intestinal pouch down to the anus, and my only hope was to maintain and dilate the sinus which I had just

made. First passing a broom-straw as a guide, I removed the canula and inserted in its place a flexible catheter with the tip cut off.

On the next day I found that the child had passed a comfortable night, nursing with appetite. No vomiting. Early in the morning the catheter was expelled, and a copious evacuation found its way through the wound. No elevation of temperature nor apparent abdominal tenderness. I nicked the edges of the perforation in the anal pouch and passed a No. 2 (French) bougie. For two weeks afterward I contented myself with the daily introduction of bougies, up to 32 (French), the patient meanwhile doing as well as could be expected, with two or three evacuations per diem; a large one always following the use of the bougie. Subsequently I made use of Thomas's dilator—an instrument resembling a slender glove-stretcher—with a view to enlarging gradually the artificial passage, and by this means was able to procure distention to about an inch and a quarter. The bowels were evacuated regularly and freely, and with normal action of the external sphincter; but the general condition of the patient remained discouraging, notwithstanding that it nursed with avidity and retained the milk without trouble. There were, however, no marked indications of failure until the sudden and severe onset of cold weather in the beginning of January, under which, in an insufficiently warmed cottage, the child rapidly sank, dying of asthenia on the morning of January 3d, six weeks after the operation. I was unfortunately unable to procure a post-mortem examination.

The fatal termination of this case cannot be regarded as a disappointment, considering the condition of the child when I first saw it, and its unfavorable surroundings; yet the operation itself may be called a *quasi* success, all of its dangers being passed, and the immediate cause of death unquestionably being the exceptional cold of the night of January 2d acting upon a feeble and ill-protected frame. I have been induced to report the matter fully, partly on account of the unusual depth of the exploratory puncture, partly because it illustrates some of the difficulties attending the choice of an operative procedure in similar deformities.

It is to be remembered that in the development of the fœtus the lower portion of the rectum is a pouch formed from the outer layer of the blastodermic membrane, while the middle portion of the primitive intestine, a closed sac, from which are to be formed the small and large bowel, down to the upper part of the rectum, is contained in the umbilical cord until the fourth month, its lower extremity subsequently constituting the cæcum, which lies at first in the mesial line, and from whence the colonic arch is projected, not reaching its full development, however, until the sixth month. A separate segment of the primitive intestine—the pelvic portion—is charged with the production of the middle third of the rectum. Hence we can readily understand the various degrees of malformation resulting from arrest at different stages of evolution. From the simple cutaneous closure of the anal orifice up to a series of detached pouches, or to abnormal openings at the umbilicus or into the uro-genital tract, pathological anatomy shows us every grade of deformity. The most easily remediable of these conditions is where the abdominal portion of the intestine and the anal portion of the rectum have reached each other but failed to completely coalesce, leaving a membranous septum where the two pouches came together. This condition is not difficult to recognize, from the sense

of fluctuation imparted by the accumulation of mœconium; and the mere division of the septum, with subsequent dilatation, will suffice to establish the natural order of things. But where the separation between the two pouches is of greater extent, the problem becomes vastly more intricate. We may have a fibrous cord—the remnant of the undeveloped pelvic portion of the primitive intestine—leading to a normally situated sigmoid flexure, or a mass of cellular tissue reaching up in the pelvis to an indeterminate extent, the blind termination of the upper bowel being anywhere between a centrally placed cæcum and the normal side of the descending colon. This uncertainty affords the strongest argument against Callisen's—or, as it is commonly called, Amussat's—operation of left lumbar colotomy, and leaves the balance in favor of Littre's proposal to make an opening in the left iliac region, where, even if the sigmoid flexure be absent, some coil of intestine can be reached. But in all such cases the question arises, whether death be not preferable to the chance of a life burdened with the disgusting condition of an artificial anus. Moreover, neither of these operations has yielded encouraging results when performed for congenital deformity; most of the patients having died within a few days. The only really satisfactory instances that I know of are those of a girl operated on by Duret in 1793, by Littre's method, whom Gerraud (quoted by Velpeau) saw alive and well twenty-one years afterward; and a boy mentioned by Erichsen, on whom lumbar colotomy had been performed eight years before for congenital absence of rectum and anus. A few other "successes" are vaguely reported, but the lapse of time between the operation and the report is either not stated at all, or is so brief that the permanence of the success is left in doubt. At all events, with the exception of Gerraud, I know of no one who has met with an adult bearing an artificial anus established for the relief of a defective rectum at birth.

Most modern surgeons agree in advocating the perineal operation, though this also has failed to prolong life for more than a few weeks at most in the vast majority of instances; the few examples of more lasting benefit being where the intestine lay but a short distance from the sphincter, save in a case operated on by M. Friso (recorded by Velpeau), where the wound extended to the depth of three inches and a half. In this case, however, the duration of life is not given.

Theoretically, the most favorable results should be obtained where the bowel lies near enough to permit its extremity to be brought down to the external orifice, thus establishing a continuous mucous canal—as was first, I believe, done by Amussat in 1835. But even here, few patients have survived more than three or four months at longest. When the interruption of continuity is greater, as in the case I have related, all that can be accomplished, whether by trocar or bistoury, is to create a fistula which must have a constant tendency to contract, and which, though perhaps sufficient for the semi fluid discharges of infancy, will almost inevitably give rise to trouble when the feces become more consistent. It was for this reason that I attempted, though with small hope of ultimate success, to dilate the artificial canal to the utmost by the "glove-stretching" process. If the external anus were absent the better plan would be to dissect inward with the bistoury, using the finger as a guide; but where a normal anus exists, I should prefer to explore with the trocar, forasmuch as a smaller wound is made if we fail to reach the intes-

tine, while, if the latter be found low enough down, the knife may be employed to complete the operation. The chief drawback to the trocar is the difficulty of making sure that the lowest available point of the bowel is entered. In my case, in lack of an autopsy, I cannot tell what part of the intestine I perforated, and can only surmise, from the extent to which a bougie could be passed, that the descending colon terminated in a large cloaca.

The deaths in nearly all the cases which I find recorded have been from asthenia, and I believe that the alleged source of danger from absorption of septic matter in the perineal operation is imaginary rather than real. There is nothing necessarily septic in the feces while in the intestine, and we do not fear their contact with a wounded surface in other operations about the rectum. At any rate, in the instance under consideration, there was no indication of blood-poisoning, notwithstanding the somewhat rough usage to which the track of the wound was subjected.

To sum up, it seems to me that the following propositions may be stated:

1. In congenital malformations of the rectum, exploration from the perineum should always be first essayed, and by preference with the trocar. If the occlusion consist of a simple membranous septum, it need only be incised crucially with a probe-pointed bistoury. If the intestinal pouch be sufficiently near to the surface, the track of the trocar should be enlarged by the knife, and an endeavor made to bring the mucous lining down to the external wound. If, however, the interruption of continuity be too great for this proceeding, we should be content with dilatation of the fistulous passage, although with small chance of prolonging life beyond a few weeks.

2. In case of failure to find the bowel with the trocar, a forlorn hope may be sought in colotomy. And here, in view of the probability that the arrest of development has occurred at an early stage, I should choose the right lumbar region as the site of operation.

3. Where the deficiency of the rectum involves a considerable part of its course, the prognosis is almost hopeless, whatever method of operation be adopted.

CLINICAL CASES.—I. LOCAL USE OF ERGOT. II. GUAIAECUM IN HEMATURIA.

By JOHN N. UPSHUR, M.D.,

RICHMOND, VA.

CASE I.—I was called, on the 4th of March, 1878, to see Mrs. E. S—, who gave the following history of herself:

"I am 32 years old; married eleven years; have never had any children. Have been very irregular in my menses, and suffer more or less constant pain in my left side, pain in my back, and sense of weight in the lower part of my stomach; when the time for my period comes, I spit some blood and have an uncomfortable sense of fulness about my head; of a constipated habit, though bowels are moved daily, insufficiently; at each stool lose more or less blood; it is sometimes so free as to blanch the cheek; have suffered with this hemorrhage from the rectum for twelve years, and it is always increased by any undue exertion."

At the time of my first visit, her complexion was

sallow, appetite capricious, and a general feeling of indisposition to make any exertion. Had been under the care of two other physicians of this city. Vaginal examination revealed a womb somewhat prolapsed, enlarged, and os abraded, extending up the cervix nearly to os internum; some leucorrhœa. Rectal examination showed an ulcer just on the margin of the internal sphincter, with edges abrupt, as if cut out with a punch, about four lines in diameter, and springing from the bottom of it a pyramid of granulations which bled profusely on the slightest touch. She was put upon a general tonic treatment of iron and the hypophosphites, undue exertion prohibited, and the bowels kept in a soluble condition by laxatives and enemata. Her womb trouble, under the local application of Churchill's tincture of iodine, glycerine balls, and the hot douche, was soon relieved, and the application of a Hodge pessary, which was worn for about six months, entirely restored this organ to its normal condition.

All sorts of applications—both caustic and of a soothing and astringent character—were made to the rectum, but with only temporary benefit; the hemorrhage not being restrained for more than a week or ten days at a time, and the ulcer obstinately refusing to heal. There was an attempt at the perfect restoration of the menses, but this was not accomplished so long as the hemorrhage from the rectum continued. After a month or two of this treatment (she having been very averse to the knife), assisted by my friend Dr. Hugh M. Taylor, of this city, I freely divided the sphincter muscle, and kept her in bed for ten days. From this treatment she derived much benefit, and had a longer exemption from the rectal hemorrhage than ever before; the menses became more regular, and her general health improved, and in October I discharged her, flattering myself that she was permanently cured. But the hemorrhage continued to recur at intervals of three to five weeks, and in July, 1879, she again came under my care for treatment for the old trouble. Examination of the rectum showed the old ulcer healed, but the lower end of the incision made a year before was still open, and manifested no inclination to repair. Just at the margin of the internal sphincter muscle, about the site of the old ulcer, there was a villous tumor about the size of a nutmeg, with sessile base, and very red in appearance. A few applications of Batey's solution No. 2 (iodine, ʒ ij, and liq. carbolic acid, ʒ vi.) soon healed the old cut, but the bleeding recurred, and no local application that I could make was of any benefit to it. Having had my attention called several years ago to the injection of ergot into the rectum in the treatment of piles, by reading a report of the successful treatment of some cases of this malady with this agent, by Dr. Semple, of Hampton, Va., and more recently by a paper from the pen of my friend Dr. Wm. C. Dabney, of Charlottesville, Va., on the local use of ergot, I determined to give it a trial, ordered a suppository composed of gr. xx. ext. ergot, with some anodyne and cocoa-butter, to be introduced twice daily, and kept the bowels open by co. senné powder taken at night. One week of this treatment had reduced the tumor to half its original size, and it presented a pale, withered appearance; *no hemorrhage*. At the end of the second week still more improvement, and the patient expressed herself as greatly comforted. Directing her to continue the suppositories and let me know if she stopped improving, I discontinued my attendance. Nov. 25, 1879, visited Mrs. S— to-day; says she has had *no bleeding for four months; thinks herself entirely well. Menses regular* and normal, and

declares that *she feels better, can walk and exert herself more than ever before.* She still uses the suppositories as a matter of precaution.

CASE II.—Was called, in January, 1878, to see Miss E. H.—, æt 29, by occupation a seamstress. She was up, and engaged as usual with her needle. Had been previously healthy, except that about a year before she had had an attack of hæmaturia lasting for several months, resisting all treatment, though she was attended at the time by a man of skill and long experience, and finally stopping of its own accord.

The writer was called in to prescribe for the same trouble, which had recurred without, so far as could be ascertained, any cause. Her family was of an intensely rheumatic and gouty diathesis, though not one of them a free liver. No cause being apparent, the treatment was difficult; and she took for three months various treatment—tonic, ferruginous, diuretic and astringent—with varying results, and at the end of that time was no better than in the beginning. Analysis of the urine at various times, chemically and by the microscope, kindly made for me by Prof. L. S. Joyes, of this city, failed to reveal *anything* save evidence of the presence of blood. Every treatment that the writer could think of—all the suggestions made by some of the best men of the profession in Richmond—were tried, with *no success* whatever.

At last, being in despair, and “necessity” in this case as many others in life proving to be “the mother of invention,” I determined to try the tinct. of guaiacum, for the sole reason of its reputation in the treatment of congestive dysmenorrhœa, tonsillitis, &c., and because I believed the hemorrhage might be kept up by a passive congestion of the kidneys. A drachm three times a day in half a tumbler of milk was ordered, and at the end of the second day the hæmaturia had entirely ceased, and did not return again for a year, when, on her own motion, she took the tinct. of guaiacum again, in the outset with the same prompt relief, and has since had no further trouble.

This case was reported to the Richmond Academy of Medicine; and the result obtained in the above case, subsequently confirmed by Dr. J. G. Cobell, of this city, in a case of his, the hæmaturia being checked in *two days*, all previous treatment having failed, and in *two* similar cases under the management of Dr. H. H. Levy, also of this city. I do not attempt to explain the *modus operandi* of this remedy, but make only a simple unvarnished statement of facts; and if I can add a remedy in the treatment of this malady, which, by further trial, will prove as beneficial as in these few cases, I shall be more than repaid. Every new fact in the experience of any medical man who loves his profession, and would thereby benefit humanity, ought to be given publicity to that end, and it is such a motive which has prompted the report of the above cases.

615 E. FRANKLIN STREET.

◆◆◆◆◆

SIMPLE METHOD FOR THE TREATMENT OF PURULENT OTITIS.—In place of a syringe and a tampon of cotton, one can use a round piece of wicking. This may be introduced by the patient himself with a gentle rotary movement. After it has reached the bottom of the ear, it quickly absorbs the pus and is then to be drawn out. The movement is then repeated until the ear is clean, when a fresh piece of wick is left instead of the conventional cotton. The wick may be medicated with an alkaline solution or with common salt.—*Gazette Hebdomad.*

Progress of Medical Science.

DIPHTHERIA AND MILK.—There has long been a suspicion that milk was occasionally a carrier of the diphtheritic poison. It has even seemed probable that the diphtheritic poison originated with some morbid condition in the cow itself. It was shown in 1869 by Dr. Thorne that the milk from cows affected by foot and mouth disease was injurious to human subjects. About a year ago a committee of the London Pathological Society was appointed to investigate the relation between milk and diphtheria. Their work is not yet finished, but meanwhile several outbreaks of diphtheria have occurred in England, which show the importance of a more thorough knowledge of the matter. The history of these outbreaks has been given by Mr. E. L. Jacob.

On a particular day ten persons in the village of Weybridge were attacked with diphtheria. During the subsequent nine days fifty more had the disease. The epidemic then suddenly stopped. The persons affected were mostly of the better class, and were found to be living in all parts of the village. The only thing in common was, that all the families affected had milk from the same dairy. Twenty per cent. of the families supplied by this dairy had diphtheria. Eleven of these families had milk from two or three cows exclusively. Ten out of this eleven had diphtheria. The remaining 139 families supplied by this dairy had more or less of the milk from the same two or three particular cows. Twenty-one of these 139 families were attacked. The evidence pointed with great certainty toward the milk as the source of the infection, and, with less probability, toward the two or three selected cows. Investigation failed to discover any disease in the cows, or any especially bad hygienic condition about them. It was possible, however, that the cows had had some disease, or that the milk had been diluted with polluted water.

At the Princess Mary's Village Homes forty-eight persons were attacked with diphtheria. The water-supply of the farm which supplied the milk to the homes was found to be impure; one of the cows had the garget; and the epidemic began rapidly to decline eight days after the stoppage of the milk-supply.

In these cases the evidence is not so strong that milk was the cause. Still there was nothing to which the epidemic could be attributed.

At Leatherhead, in the course of six weeks, fifty-five persons were attacked with diphtheria. As respects water-supply, drainage, school-congregation, and personal infection, there was very little in common. Almost all of the families affected, however, had milk from the same dairy. Nothing wrong could be discovered at this dairy, except that the water-supply was not very good.

At Sutton, fifteen persons were attacked with diphtheria within two days. These persons lived in different parts of the town, and under good sanitary conditions, but they were all supplied with milk from the same dairy. Nothing wrong could be discovered at this place.

The facts thus given, though inconclusive, have very great importance as showing the necessity of a thorough investigation of the true relation of milk-supply to diphtheria.—*Brit. Med. Journ.*, Nov. 8, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

W.M. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 13, 1879.

ASYLUM MANAGEMENT.

NOTWITHSTANDING the report of the Senate Investigating Committee, referred to in our previous number, the medical profession should not be discouraged in continuing its efforts at reform in insane asylum management. The fact that the petitioners from the New York Neurological Society did not make out a case, simply proves that they came before the Senate committee unprepared for the investigation. But reforms in asylum management are still as necessary as before, and must continue to be urged even at the disadvantage of being against what now appears to be present public opinion.

In view of this necessity, it is encouraging to know that a number of influential citizens, representing all the professions, have taken the matter in hand, with a determination of suggesting the necessary reformatory measures and enforcing their consideration upon our legislators. Public opinion is to be created in favor of the movement in another manner than that of making the asylum superintendents the apparent martyrs to personal animosities. On previous occasions we have pointed out the deficiencies in asylum management, and it may not be amiss to direct attention to them again by way of suggesting to the citizens' committee the propositions the verification of which would promise the best practical results.

Most insane asylums are too large for efficient management; and yet they are in nearly every case greatly overcrowded. A great proportion of our State insane are in poor-houses or wretched county asylums, where they get practically no treatment at all. Only two of our county asylums are efficiently managed. The number of attendants in asylums is small, and, in some instances, their training insufficient. There is, in consequence, too much mechanical restraint; there is not enough systematic exercise, amusement, or employment; the present system of medical care is inefficient; the acute and chronic insane are treated together, and it is now pretty gen-

erally agreed that this should not be done. The provisions for early treatment of the insane are entirely inadequate, although its great importance is everywhere acknowledged. There is, in many cases, need of better diet, and of proper appliances of every kind. Few institutions are capable of doing any good pathological work.

We can, in addition, make the general complaint that clinical and didactic instruction in insanity is at its lowest possible ebb, and it is for this reason, in part, that so little attention or interest can be aroused among medical men on the subject of lunacy reform.

The measures which both the profession and the public should strive for ultimately should be: The establishment of lunacy commissioners, who should devote their time exclusively to the work of overseeing the asylums; the erection in future of asylums that shall be economically built, and shall not accommodate over 250 or 300 patients; the reorganization of the medical and executive arrangements for the management of the institution. This should include a fuller and a better paid, and, if possible, a better qualified medical staff. There should also be a visiting staff, when practicable—one that would be something more than a mere ornamental appendage. There should be trained nurses in numbers sufficient to make mechanical restraint a rare necessity. There should be arrangements for treating the acute and chronic insane in separate institutions, and for getting the acutely insane under treatment as soon as possible. The medical profession should join the public in demanding that measures for securing these reforms be instituted as soon as possible. It should ask, also, more exclusively on scientific grounds, that the clinical and pathological material be utilized as much as possible for the benefit of students and physicians. It may appear that these best methods, suggested above, are very Utopian. There is not, however, anything intrinsically difficult in carrying them out.

The trouble lies in the political influences that surround present institutions, in the fact that old methods have been firmly engrafted upon us by time, and through the existence of large and expensive buildings in which the old routines are established. The question of money, which a reform always at first requires, is also a prominent one.

There is, however, the fact that these evils do exist, and are crying ones. There is the fact that improvement is not at all impossible. These things will give encouragement that something will eventually be accomplished. When fully known and appreciated, no civilized and humane community will long tolerate them.

GRATUITOUS SERVICES TO CLERGYMEN.

Our esteemed contemporary, the *Philadelphia Medical*, has in a recent number a very sensible editorial

article on the gratuitous treatment of clergymen. It is the practice, generally, whenever attendance is given to a minister's family, never to demand pay therefor. A great many practitioners have been at a loss to understand why such a distinction should be made in favor of this particular class of professional gentlemen. If they are poor, then of course the physician is only too ready to attend them for nothing. It is true, the clergyman is a man of influence in the community, and the young practitioner is generally glad to have it known that he has his confidence. But practice obtained in that way is generally not worth a great deal, especially if the unfortunate practitioner has the representatives of all the denominations of his village on his list. Even then it is quite likely that his distinguished patients may recommend some quack to his parishioners, especially if that individual has made a fortune, and is a prominent pew-holder in the church. We are sorry to say it, but the medical profession really owe very little to the clergymen. The good influence which might be exerted in behalf of legitimate medicine is thrown into another channel, and charlatany is endorsed not only in religious papers, by widely circulated certificates of remarkable cures, but even in the pulpit itself. Of course, there are notable exceptions to this rule, but we are speaking of clergymen as a class. When we look at this question in a purely matter of fact light, there is no real reason why a clergyman should be free from pecuniary obligations to the profession. If the physician wishes to aid the cause of Christianity by caring for its servants, he can do it in the ordinary way. The assumption of more than this obligation by holding himself out as a general dispenser of charity to the clergy, not only gives him more than his share of good works, but imposes upon his professional brethren an extra burden, which to refuse might be considered heathenish.

We are not talking of poor and really deserving clergymen; but of those who have as large, or, as is very often the case, larger incomes than the physician who attends them. In such cases we are constrained to ask, where is the return for services rendered? Pecuniarily speaking, does the doctor get an equivalent in the free services of the minister? This question is answered in part by the following remarks of the editor of the *Times*:

"If the physician attends church—and let us hope he does—he assists in paying his minister's salary. If he marries—and let us again hope he does—he pays his minister a fee which five times exceeds what he would ask for granting the clergyman a similar amount of time. In case of death in his family, he perhaps would hardly feel comfortable unless he sent his minister a fee for his services at the funeral. Now the real question arises, why should he not receive a reward for his services when the minister calls for them?"

THE WAY TO SELECT A PROFESSOR.

A NEW departure is to be made in Chicago in the selection of a professor for one of the medical colleges of that city. It is announced, as will be seen in another column, that a public *concours* is to be held for the position at a certain time next month, the candidate lecturing on a subject previously selected before the faculty and the medical class. Applications are received from any part of the country. We speak of this plan for the purpose of giving it an unqualified endorsement, and hope that the example will be followed by all the medical schools in the East. If the college does not succeed in obtaining a first-class teacher, it will not be because it has not made an honest effort to do so.

We hope that there will be a great number of applications, so that a good opportunity will be offered for a proper selection. We shall await the result with considerable concern, as its success will serve to establish a very praiseworthy precedent.

PERCENTAGE FROM DRUGGISTS.

We are informed by the *Chicago Pharmacist* that many of the physicians in Chicago demand as high as forty per cent. on the gross price of their prescriptions to patients, others as low as twenty-five per cent., while still others are content with their cigars and liquors free. If this be true, many of the physicians in Chicago are in a very bad way. We are inclined to think that the statements must have some foundation in fact—if not in Chicago, at least in different parts of Michigan, for the *Michigan Medical News* comes forward to excuse the evil. While the editor does not endorse the practice, he rather boldly says "that there are circumstances in this country and in these times which remove it from the realm of moral turpitude." These circumstances appear to be, that the honest and conscientious doctor cannot collect all his bills, and must therefore have a "collusion with the druggist." "What with dead-beat patients and prescribing druggists, the physician is but too often driven to 'execute the villany he is taught.'" The inevitable conclusion appears to be, that if the balance is to be struck against such patients as will not pay, and against the druggists who will prescribe, the burden is narrowed down to the conscientious patient who not only pays his doctor, but also the druggist and the percentage. Verily, we believe that it is time for the golden geese in Illinois and Michigan either to migrate or stop laying.

SANITATION AT MEMPHIS.—A citizens' committee, at a meeting in Memphis, November 30th, adopted the recommendations of the National Sanitary Commission in regard to sewerage and the general sanitary care of the city. Efforts are to be made to obtain money of the Legislature for carrying out the proposed measures.

Reviews and Notices of Books.

THE HISTORY OF MEDICINE IN NEW JERSEY AND OF ITS MEDICAL MEN, FROM THE SETTLEMENT OF THE PROVINCE TO A. D. 1800. By STEPHEN WICKES, A. M., M. D., Acting and Honorary Member of the Medical Society of New Jersey, etc. 8vo, pp. 449. Newark, N. J. : Martin R. Dennis & Co. 1879.

In the year 1875 the Medical Society of New Jersey resolved to publish its old transactions, and by virtue of his official relations to the Society, Dr. Wickes became the editor of the volume. What appeared to be an accident in the beginning turns out to be a very fortunate thing for the Society and the profession. Dr. Wickes has given us, as the results of his careful research and patient labor, one of the most interesting volumes which it has been our fortune to read. Commencing with the beginnings of population in New Jersey, he tells us what was the early medical practice in the province, and gives an intelligible and succinct account of the different diseases which were prevalent at that period. The history of inoculation as practised in New Jersey claims attention. The account of the formation of the first medical societies, and of the conditions of medical literature and education, are extremely instructive to the medical historian, as showing how keenly alive were the forefathers in medicine to the necessity of maintaining the reputation for learning and the dignity of their calling. The story of legislation is full of suggestive references to past history, which is now and again repeating itself in different medical organizations over the country. The practice of obstetrics was, to all accounts, in an exceedingly crude state, and we have a short account of the first efforts at teaching this branch of our art. The condition and management of the military hospitals recall some incidents of the American revolution, as do also the biographies of a host of medical authors, which till the latter half of the work. A paper entitled "Observations on that terrible Disease vulgarly called the Throat Distemper, by J. Dickinson, A. M.," and written in 1740, is an interesting document, and gives a good idea of the crude notions of pathology and therapeutics which prevailed at that period. The fee bills which are published in full, as well as the accounts of some of the old fathers, help to make instructive history in regard to methods of practice and the charges therefor. But it is impossible to detail the excellences of this instructive history; it is, perhaps, sufficient to say that the accomplished editor deserves the thanks of the entire profession for the admirable manner in which he has performed his task.

WALSH'S PHYSICIAN'S HANDY LEDGER. Ralph Walsh, M. D., Washington, D. C.

This is an exceedingly handy, simple, and convenient ledger. It is intended as a companion to the call-book and tablet by the same author, but can be used with any visiting-list desirable. Each page is devoted to one patient for the year, there being spaces for each day of the month. The amount per month can be footed up at the end of each month-line, or the whole amount of the year's attendance can be given at the foot of the page. Spaces are also made in appropriate places for a credit account, monthly or yearly, with date of payment. By this arrangement the physician can tell at a glance on what particular days he made his visit, how many

per day, and when the patient paid him on account, and the amount. Facing each patient's page is another, on which is noted obstetrical, surgical, and miscellaneous attendance, for which special charges are made. The general plan of keeping accounts is otherwise the same. It is substantially bound, has good paper, clear type, and is altogether a serviceable volume.

ATLAS OF HUMAN ANATOMY. Containing 180 large plates, arranged according to Drs. Oesterreicher and Erdl. from their original designs from nature, with full and explanatory texts by J. A. JEANÇON, M. D. Cincinnati, Ohio: A. E. Wilde & Co.

The object of this work, as stated in the preface, is to "bring before the medical public a pictorial representation of all parts of the human body in a size and form which ordinary works on anatomy fail to furnish." We have received the prospectus, which contains a life-size engraving of head, neck, and shoulder, showing the distribution of the carotid, subclavian, and axillary arteries. The figure is artistically drawn, is printed on fine paper, and is accompanied with explanatory text. As far as can be judged from this specimen, the work will be a very valuable one.

THE SKIN AND ITS TROUBLES. New York: D. Appleton & Co. 1879.

Thus, the eleventh of the English Health Primers, is presumably written by Tilbury Fox. The skin is shown to be a much-abused organ, and many points instructive to the laity are given. The necessity of attention to the constitutional condition in skin diseases is insisted on throughout the book.

FIRST BOOK OF QUALITATIVE CHEMISTRY. By ALBERT B. PRESCOTT, Professor of Applied Chemistry in the University of Michigan, etc. 8vo, pp. 160. New York: D. Van Nostrand. 1879.

PROF. PRESCOTT has prepared this little manual for classes which take a short course in qualitative chemical work. Although for such purpose it is much fuller than is absolutely necessary, the general design and arrangement are very good. The book will, no doubt, prove very useful to the many who can never expect to gain more than superficial acquaintance with experimental chemistry.

PHYSICIANS' POCKET DAY-BOOK. By C. HENRI LEONARD, M. A., M. D. Detroit: C. Henri Leonard. 1878.

DR. LEONARD has furnished the profession a very good day-book. It contains also a small ledger, and is probably quite complete enough to serve all the purposes of our young men "with a small but growing practice."

PREVENTION AND CURE OF CHRONIC CONSUMPTION. By DAVID WARK, M. D. 8vo, pp. 103. New York: The Authors' Publishing Co. 1880.

STARTING with Hutchinson's tables, which show that the vital capacity of the lungs steadily decreases with the progress of consumption, the author assumes that proper physical training will prevent this decrease and stop or cure the consumption. This theory is padded with a mass of physiological facts and fancies, and ornamented with a recital of several private cases that have been cured by the new treatment. The author has evidently crammed up a good deal on physiology, and though he has not yet got the science quite clear in his head, his statements are tolerably accurate. They will probably impress the

public, for whom the book is designed. The history of "cases cured" will also make a very effective appearance.

To the profession the book presents nothing new—except its author.

STUDENTS' AID SERIES: AIDS TO ANATOMY. By GEORGE BROWN, M.R.C.S., etc.

AIDS TO FORENSIC MEDICINE AND TOXICOLOGY. By W. DOUGLAS HEMMING, M.R.C.S.

AIDS TO THERAPEUTICS AND MATERIA MEDICA. Part I. The Non-Metallic and Metallic Elements; Alcoholic and Etherial Preparations, etc. By C. E. ARMAND SEMPLE, M.R.C.P., London. New York: G. P. Putnam's Sons, 1879.

The Students' Aids Series is an American reprint of a number of small works by English authors. Most of the books have had considerable popularity in England, and they are likely to meet the same reception here. They are written by reliable men, and are printed in excellent style. Not much can be gotten within sixty or seventy pages, however, and their value, except to assist in "cramping," is slight.

Of the three before us, that on Forensic Medicine covers ground not in the text-books ordinarily purchased by students, and is of more value on that account.

We confess we are unable to find anything specific to praise in the other two books.

HYGIENE OF THE VOICE: ITS PHYSIOLOGY AND ANATOMY. By GUISLANI DURANT, M.D., Ph.D. A New and Revised Edition. 8vo, pp. 189. New York: Cassell, Petter, Galpin & Co., 1879.

DR. DURANT'S treatise on the Hygiene of the Voice covers very nearly the same ground as that of Mr. Holmes's book recently reviewed by us. It is, however, less pretentious in its composition; it contains less historical matter, and the subject is not so elaborately analyzed and classified. The physiological discussions, we may add, are also less thorough, and the anatomical plates and descriptions not so good. The present work, however, is full of useful suggestions, and altogether is a more practical and useful volume. A very clear and satisfactory account of the vocal organs is given, this occupying about half the book. The rest of the space is devoted to hygiene. Under this head the doctor makes some special attacks upon customs not unfrequently indulged in by speakers and singers. Cold drinks, tight lacing, the wearing of red flannel, whispering, loud talking, and laughing—above all, the use of troches, are interdicted. As a substitute for the latter to lubricate the throat, the author uses a mixture of *pimpinella saxifraga*, *pulmonaria*, *erysimum*, and bromide of ammonium, held in gum acacia.

Some curious facts in regard to the eating and drinking habits of noted artists are given. Thus, in the intervals of rest during exercise of the voice, Wachtel swallows the yolk of an egg beaten up with sugar; Mme. Sontag eats sardines; Mme. Patti drinks seltzer water; Mme. Nilsson, beer; and Lablache eats two salted cucumbers. The tendencies seem to be, on the whole, towards beer and tobacco.

In an appendix to the book, a number of formulæ for colds, sore throat, etc., are given.

The publishers have done their work extremely well, and made the book a model of neatness.

THE THROAT AND VOICE. By J. SOLIS COHEN, M.D. Philadelphia: Lindsay & Blakiston, 1879.

This is one of the series of American Health Primers. It is more of a medical book than is that of Holmes

or Durant, the first half being devoted to short descriptions of diseases of the throat and larynx. As these descriptions for the most part end in recommending—very properly—that a physician be called in, their exact utility is not very apparent. The rest of the book is devoted to the physiology and hygiene of the voice. The author's name is sufficient guaranty that the work is well done.

There are a number of good illustrations.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Nov. 20, 1879.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

The Academy was called to order at 8.15 P.M., and the minutes of the last stated meeting were read by the Assistant Secretary, Dr. EDWIN F. WARD.

The Librarian, Dr. JOHNSON, reported that, since the last stated meeting, the library had received seven bound, four unbound volumes, twenty-eight pamphlets, twenty-seven numbers of medical journals, and an atlas containing ten micro-photographs, a present from Dr. John P. Gray, of the State Lunatic Asylum.

On motion, the thanks of the Academy were extended to Dr. Gray for his valuable contribution.

THE PRESIDENT then introduced Dr. Stoddard, of Michigan, and Drs. White and Alden, of the U.S.A., and invited them to take seats upon the platform.

The Statistical Secretary, Dr. F. V. WHITE, announced the death of Dr. Oliver White, and gave a brief sketch of his life.

The President appointed Dr. Gouverneur M. Smith to prepare a memoir of the late Dr. Oliver White.

LUMBO-COLO TOMY FOR NON-MALIGNANT DISEASE.

DR. A. C. POST presented a patient upon whom he had performed lumbo-colotomy (vid. page 560).

DR. LEWIS A. SAYRE thought the case presented by Dr. Post marked a new feature in American surgery; for he knew of no case in which the operation of lumbo-colotomy had been performed in a case of non-malignant disease. He was not able to see any difference between malignant disease and an incurable disease, so far as the propriety of an operation for relief was concerned; if any, it should be in favor of the latter; for by its years of otherwise unavoidable suffering might be avoided. He thought the operation under the circumstances was perfectly justifiable; it was in accordance with a principle, and he believed it was original with Dr. Post.

DR. POST remarked that Dr. Van Buren had expressed himself entirely in favor of the operation under the circumstances mentioned.

DR. HOWE referred to a case which he reported to the New York Pathological Society last winter. The patient had a history of syphilis, her vagina was almost entirely closed as well as the rectum; she was emaciated and bed-ridden. The operation of lumbo-colotomy was performed after consultation; it resulted in complete relief, and the woman was yet alive and enjoying good health. Subsequent to the operation her rectum and vagina became completely closed.

EXCISION OF THE HEAD OF THE FEMUR IN UNUNITED
INTRA-CAPSULAR FRACTURE.

Dr. J. W. Howe read a paper on the above subject, basing it upon a case which came under his observation in Charity Hospital, and had the following history: A female patient, *æt.* 62 years, was admitted to Charity Hospital March, 1876. No hereditary taint of any kind, except the love of whiskey. Three months previous to her admission she received an intra-capsular fracture of the neck of the femur by falling at the doorstep, and was treated eleven weeks by means of Buck's extension apparatus at the Chambers Street Hospital, after which she was sent to Charity Hospital. When admitted to Charity the limb was not painful when at rest. A plaster-of-Paris splint was adjusted and worn two months without improvement. It was removed, and Buck's extension with the long splint substituted and worn for six weeks, but without benefit. The limb was suspended by means of a broad bandage passing under the foot and up around the neck, and the patient placed on a pair of crutches, but that failed because of the pain produced, and the patient again took to her bed. Crepitus was as well marked as at the beginning of the treatment. The patient remained in bed eleven months afterward, without improvement. Finally, excision, with the patient's consent, was performed. When the joint was opened about a drachm of what seemed to be inspissated pus mixed with a small quantity of bony débris was found. The neck of the femur was completely absorbed. There was nothing left of the globular head. There was also found a thin, sharp spiculum of bone, about an inch in length, which belonged to the lower fragment. The head of the bone was easily loosened and removed, and the spiculum of bone and the broken-down material in the cavity of the joint. Buck's extension was applied, and a long side-splint, and the apparatus was kept in position six weeks. A plaster-of-Paris splint with a large fenestra was then adjusted, which enabled her to move about a little upon crutches. The plaster splint was worn two weeks, when it was renewed because the first one produced some irritation at certain points. At the end of three months the wound was completely healed, the patient was able to get in and out of bed without assistance, was free from pain, and able to walk with crutches. The knee-joint remained considerably stiffened, and was somewhat painful.

Dr. Howe thought that trouble would have been avoided by operating twelve months previously, before the muscles and anatomical structures of the knee and ankle-joints became affected, as they necessarily would by disuse, etc. It is two years since the operation was performed, and the patient is in excellent physical condition, and able to go about comfortably by the aid of crutches. The muscles of the limb are gaining strength, and are in better condition than when the operation was first performed. The knee-joint remains stiff. No pain at the hip, except on forced flexion or abduction.

He thought the operation was justifiable in cases of intra-capsular fracture of the neck of the femur occurring in persons in good general condition: under antiseptic treatment it was safe; and it afforded as complete relief as if the fracture had united in the beginning by firm ligamentous union.

His argument was as follows: In intra-capsular fracture of the neck of the femur, ligamentous union is the best result that can be obtained, no matter what treatment is adopted. In a large number of

cases no union ever takes place, and in this class of cases the patients are helpless and bed-ridden from the beginning.

Absence of attempts at union commonly arise from the following causes:

1. Superficial caries of the fractured ends of the bone, especially affecting the upper fragment in consequence of small blood-supply.

2. The necrosed portion of bone acts as a foreign body and excites inflammatory action in the adjacent bony tissue, and ultimately brings about complete destruction of the upper fragment; much of it is absorbed, but much remains.

3. Irritation and inflammation of the surrounding soft parts produced by injuries inflicted by sharp spiculae of bone belonging to the lower fragments. These were the important causes; but malnutrition, senile atrophy, non-approximation of fragments, etc., preventing repair of bones in other parts of the body, were not to be excluded, yet excision was performed for their relief.

A good result had been obtained in the one case in which the operation had been performed, but that fact did not prove that success would attend all other operations of like character. He thought, however, that sufficient information had been gained to enable him to say that in certain well-defined cases of incurable intra-capsular fracture of the neck of the femur, excision was a justifiable operation.

The paper being before the Academy,

Dr. L. WEBER remarked that, without personal experience, he was inclined to adopt the views of Dr. Howe; that is to say, if, in any given case, proper methods of surgical treatment had been employed for a reasonable length of time, the surgeon should neither fear nor hesitate to perform the operation; and, if performed early, certainly better results would be obtained than when delayed until the muscles have become atrophied and structures of other joints more or less involved.

Dr. THOS. SABINE remarked that he was not exactly able to see the indication for the operation proposed by Dr. Howe. In cases of non-union after intra-capsular fracture of the neck of the femur, the head of the bone undergoes one of two changes: either it becomes absorbed, or it becomes curious. In the latter case the indication, other means failing, is to operate and remove the diseased portion of bone. Such an operation has already been once performed by Texdor; suppuration followed, and the patient died on the twenty-third day.

In ordinary cases of intra-capsular fracture of the neck of the femur, efforts to secure union must be continued for two or three months, and during that time the fractured ends of the bone become rounded, and he thought it was very unusual for the condition of the parts, at the end of that time, to be such as to permit of crepitus being obtained. He did not see how the patient could be given a more solid limb by the operation than he would have if let alone. If the case reported belonged to the class in which caries and necrosis existed, he had no question but that the operation was justifiable.

Dr. LEWIS A. SAYRE remarked that he had had no experience in excision of the hip-joint in cases of simple fracture, although he had removed the head of the femur seventy-three times in cases of morbus coxarius. Texdor's operation, which Dr. S. P. Batchelder of this city had done previously, he did not regard as proper excision, for in his case as well as in Batchelder's there was simply dilatation of the fistula and removal of the loose head of the bone.

His own experience had been that, with proper treatment, union in cases of intra-capsular fracture was tolerably fair. As for treatment where union did not occur, it seemed to him that if it was evident the source of irritation was to be permanent, even though there were no sinuses or suppuration, the operation for the removal of the source of irritation was justifiable. The principle was the same as that involved in performing lumbo-celotomy for an incurable disease. He favored an early operation; the earlier the better when it was decided that the patient was hopelessly incurable so far as the fracture was concerned, for ankylosis of other joints would take place from simple disease without inflammatory action.

Dr. A. C. Post remarked that there was no reason to doubt that Dr. Howe's patient was benefited by the operation. In the course of his remarks, however, he (Dr. H.) said that he did not see why the limb could not be made as useful as when the head of the bone was excised under other circumstances. In the great majority of cases of excision performed for morbus coxarius, it must be borne in mind the patients were in childhood or early adolescence. It certainly made a great difference in the probable result, whether such an operation was performed on a patient ten or fifteen years of age or on one sixty or seventy years of age. We should hardly expect as good results in old age as in childhood. Then, with regard to the danger of the operation, the results, so far as preservation of life was concerned, were much more satisfactory in patients under fifteen years of age than in older patients. The operation was not a very safe one in adults, especially in the latter period of adult life. He had no doubt, however, that in a case similar to that reported, the operation would be justifiable.

Dr. WHITE, U.S.A., on invitation, spoke and referred to two cases of intra-capsular fracture; in one ligamentous union occurred, and in the other—a gunshot fracture—caries resulted; the head of the bone was removed by operation, also portions of the bones of the pelvis. He thought that when sufficient time had elapsed, under proper treatment, after such fracture, and union did not occur, recourse should be had to operative measures.

Dr. HOWE remarked, in closing the discussion, that excision for caries and necrosis was common, but in his case there was neither caries nor necrosis, but it was simply an old case of intra-capsular fracture in which crepitus was present months after the injury. The point in the case was that, instead of waiting for evidence of caries and necrosis, the operation should be performed. He thought that no case had been previously reported in which bony crepitus existed and the operation had been performed for removal of the head of the bone in intra-capsular fracture. With reference to Dr. Sabine's statement that such cases were not common, that might be true with reference to private practice, but certainly in Charity Hospital, and especially in the Alms-House, a large number could be found.

With regard to Dr. Post's remark concerning mortality of the operation in patients advanced in life—he thought it was not so bad as was supposed. Besides, if it was great in adults, it could not be argued from that that the same unfavorable results would follow in this class of cases; for their general condition must be good in order to permit the operation, whereas the reverse was true in morbus coxarius—the operation was performed to improve the general condition.

After adopting a resolution that the By-Laws of the Academy be suspended for the next meeting, and that the Academy meet at 7.30 p.m. instead of 8 p.m., the Academy adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 22, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

(Concluded from page 520).

DR. MARY P.-JACOBI presented a specimen case of
GENERALIZED TUBERCULOSIS.

The patient was a boy of 19 months; was brought to the dispensary of Mt. Sinai Hospital, Sept. 22d. Had been ailing ever since attack of measles in August; lost flesh; skin became yellowish, and there was a slight cough. Examination found slight dulness and harsh respiration at the apex of the left lung, heard most distinctly in front. The abdomen was somewhat tympanitic, but there was no diarrhœa. No enlargement of spleen could be detected at this time. The tongue was clean. The child cried a great deal, and constantly wanted to eat, but showed no unusual thirst; yet the temperature was 103½°.

It was evident that the pulmonary congestion and induration constituted only one element of a more general disease, and the diagnosis hesitated between typhoid and miliary tuberculosis. On the 24th of September the spleen was found enlarged, but the harshness of respiration was much diminished. Temperature was 102¾°. Until the 8th of October the condition remained the same. The fever was always present in the afternoon, but, according to the mother, absent in the morning. On the 8th of October, however, for the first time, fever persisted all day long. On the 9th the child vomited, and its head became very hot. On the 10th the child had become drowsy and apathetic; lay passively on the mother's lap, with the head retracted and some rigidity of the neck. The face was pale and the head cool. The rectal temperature, hitherto elevated, was only 100.5°. The pupils were normal, but the respiration was of the Cheyne-Stokes' type. Total number of respirations in a minute, 26; pulse 104°, hard, and occasionally reduplicated. The respiration was harsh in various parts of the lungs. From time to time were heard puffs of prolonged expiration. The abdomen was beginning to retract.

No doubt could longer exist of the correctness of the diagnosis of general miliary tuberculosis, with commencing meningitis. On the 11th of October the pulse was very irregular; respiration regular—40 a minute; pupils dilated; child unconscious; T. 105°. On the 13th suberepant râles were heard all over both lungs, indicating commencing softening; pupils contracted; slight convulsions. Oct. 14th—Occasional rigidity of limbs and of neck; T. 99¼° in rectum. This evening had complete convulsion, and next morning right arm was completely paralyzed. Death on the 16th, at 11 p.m.

Autopsy on the 12th, at 3 p.m.: *Brain*.—Adhesions of dura mater to skull and of its internal surface to various parts of the visceral arachnoid; half a pint of serosity escaped during removal. Entire brain found highly œdematous, and surface of convolutions pale. Omit details of the convexity. At base, typical meningitis at an early stage. Pia thickened and infiltrated over interpeduncular space; also along Sylvian fissures, where it was adherent; also over base of cere-

bellum. No tubercles larger than 'pins' heads were discernible on the surface of the pia. Microscopic examination showed the pia blood-vessels of various sizes, surrounded by cords of tubercular infiltration in the lymphatic sheaths; successive cords forming a series of beads along the vessel. The opacities of the pia were caused by diffused infiltrations of cells similar to those composing the tubercular masses on the vessels. In the tip of the left temporal lobe, occupying the most anterior part of the middle temporal convolution, was a softened patch the size of a walnut; and in the anterior part of this was a cavity the size of a tilbert. The cavity evidently represented an abscess from which the contents had escaped during the removal of the brain.

The lungs were completely studded with tubercles, nearly all in caseous degeneration. A rather large, cheesy mass, surrounded by a zone of red induration, occupied the apex of the left lung. The bronchial glands were enlarged and caseous. The spleen was enlarged and also studded with tubercle. The kidneys were congested, not tuberculous. The intestine was healthy.

The case presented several points of interest: And first, in regard to the diagnosis previous to the occurrence of cerebral symptoms. The diagnosis of general tuberculosis at such stage is confessedly difficult, although of course not impossible. The enlargement of the spleen from tubercular infiltration most closely simulates that from typhoid congestion. The extension of tubercle to the intestine would, inducing diarrhoea and tympanitis, have added other difficulties to the diagnosis than such as really existed in this case. The diagnosis was, however, made before the occurrence of cerebral symptoms; and of course, after the appearance of these, became perfectly plain.

The second point of interest concerned the original focus of the tubercular infection. Evidently a broncho-pneumonia had persisted after measles, and had been the primary origin of the tuberculosis. The question arose: Were tubercles in the lungs first formed by degeneration of cells infiltrating the peri-bronchial lymphatic sheaths; and did the bronchial glands become infected by lymphatic absorption from these disseminated tubercles, and then themselves constitute foci for the infection of the brain and spleen? Or, had the bronchial glands degenerated during the broncho-pneumonia, so that the tubercular infection of the lungs was secondary, like that of the other organs? It seemed probable that the first hypothesis was the correct one. Klein's researches on artificial tuberculosis showed the manner in which pulmonary tubercle was formed in the lymph-spaces around the bronchial tubes, thus differing essentially from the tubercles of the brain, where the infiltration surrounded the blood-vessels. In the first case, the irritant exciting the proliferation of the lymph-elements passes directly into the lymph-channels in the septa of the alveoli. In the second, it circulates in the blood-vessel, and is separated by its wall from the lymph-space. The ultimate result is the same, though the tubercles of the pia have not the time to develop to an advanced stage of caseation before exciting a fatal meningitis. Hence, apparently, the reason that tubercular meningitis is always basilar; the local effect of the irritant is felt from the moment the blood carrying it reaches the vessels of the brain enclosed in their lymphatic sheaths.

The third point of interest was in relation to the abscess, taken in connection with the paralysis on the opposite side of the body. On the one hand there

were numerous cases on record where abscess or tumor of this region was followed by no paralysis. On the other hand, there is a band of fibres known as the stria cornea, which passes into the head of the corpus striatum from the tip of the temporal lobe, and which is reckoned by Meynert as one of the four parts making up the motor tract. The question suggests itself, whether under certain circumstances the complete destruction of the origin of this band of fibres would not suffice to cause incomplete hemiplegia.

Certain it is, that the abscess in question was the only definite destructive lesion existing in the brain.

EXSECTION OF THE ELBOW.

DR. L. A. STIMSON presented two specimens of exsection of the elbow. The first was removed from a lad aged eighteen years, who, when nine years of age, had an attack of scarlet fever followed by arthritis, abscess on the inner side of elbow communicating with the joint, and finally ankylosis. During the nine years following, he had frequent attacks of pain, and for their relief he eventually came to the hospital. The arm proper was atrophied, the elbow was slightly swollen, there was some lateral motion and slight crepitus. The joint was excised by the latero-posterior incision. The capsule of the joint was filled with slightly altered synovia, and the articular cartilages were destroyed in part. The coronoid process had increased in length nearly an inch, so as to block the movements of the joint entirely. The result was quite satisfactory, there being good antero-posterior motion in the joint, and little, if any, lateral motion.

The second specimen was removed by the same kind of incision, from a stout negro, a patient of Bellevue Hospital, who had been attacked with pain in the elbow five years ago, leaving the joint stiff and useless thereafter. The elbow was fixed at a right angle, was entirely useless, and there was slight lateral motion with distinct crepitus. The operation was performed on the 23d of September last. The capsule was found so thickened that the cavity of the joint was obliterated. The ulna was very much overgrown, as was also the external condyle of humerus. Three and a half weeks after the operation there was no lateral motion; there was quite free flexion and extension, and the joint was capable of sustaining a weight of ten or twelve pounds.

Dr. Stimson remarked that the patient upon whom he had performed exsection of the elbow last June, and whose case was at that time presented to the Society, was able to use her arm as if nothing had happened.

There was very slight lateral motion, but not enough to create any uncertainty.

A CHRISTIAN MEDICAL UNION.—At an adjourned meeting of medical men and students, held in the parlor of the Y. M. C. A. Hall, Fifteenth and Chestnut Streets, Philadelphia, on Wednesday evening, December 3d, it was resolved to organize an association to be known as the Medical Christian Association of Philadelphia, which shall meet annually on the first Wednesday evening in January. The committee on organization recommended the appointment of a committee of medical men to act in co-operation with the Devotional Committee of the Y. M. C. A. in organizing and carrying on such plans of work as will reach the medical students in the city and improve the condition and morals of all such by surrounding them with Christian influences.

Correspondence.

DIPHTHERIA AND BENZOATE OF SODA.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In yours of November 29th, reference is made to a communication from the minister of Russia, Mr. Shishkin, in which the benzoate of soda is recommended to the American public, through the *New York Herald*, as a remedy for diphtheria. You justly remark that “no reliable discovery in medicine remains long without being published throughout the whole medical world.” While the benevolent spirit which characterizes our representatives abroad in calling the attention of our people to new discoveries in medicine is most praiseworthy, such efforts usually result, alas! only in arousing hopes which end in disappointment. Thus, cundurango appeared with blatant claims as a specific for cancer, but now it is almost forgotten; and erythoxylon coea, while possessing some merits, does not seem to produce in the United States the beneficial effects which are said to follow its use in Peru. The laity do not seem to understand that all, or nearly all new remedies, which possess decided merits, are the subject of careful experiment, and are finally placed upon the list of permanent remedial agents.

With regard to the benzoate of soda, a notice appeared in the *American Journal of Medical Sciences* for January, 1878, giving an abstract of the results of experiments performed by Mr. J. Graham Brown, Senior President Royal Medical Society, Edinburgh, in Prof. Klebs's laboratory. He was endeavoring to ascertain what drugs seemed to have an influence over the diphtheritic process. His conclusions were believed to indicate:

“1. That the contagious fluids of diphtheria are rendered powerless to propagate the local disease after mixture for a longer or shorter time with solutions of hydrochlorate of quinia, salicylate of soda, and benzoate of soda.

“2. That the most powerful of these three is benzoate of soda.

“3. That the administration of benzoate of soda hypodermically, previous to the inoculation of diphtheria, has a power of preventing the establishment of the disease; but that this protection only extends to a certain length.

“Mr. Brown very properly remarks that it would be very rash to suppose that any one of these points has been firmly established by the amount of evidence which is contained in this research. There are so many sources of error ever present, as to preclude such a possibility. Still, however, the *uniformity of the results* obtained is so striking as to increase greatly their value.”

At the time of the appearance of the above article, I had a case of severe diphtheria under my care, and used the following as a gargle. R. Acid benzoic., ζ i.; sodæ bicarb., ζ i.; glycerin., ζ i.; aquæ, ζ ijj. M. My note-book states that the membrane was loosening on the following day, but does not refer to any special action of the gargle. The case terminated fatally, nasal hæmorrhage and vomiting of a thin, dark fluid having ultimately set in.

Benzoic acid, closely allied to benzoate of soda, was the subject of experiments made by John Dougal, of Glasgow, to determine the “relative powers

of various substances in preventing the generation of animalculæ or the development of their germs, with special reference to the germ theory of putrefaction.”* The preventive properties of sixty-seven substances, such as carbolic acid, sulphate of copper, and nitrate of ammonium, were tested by mixing solutions of them respectively with a filtered solution of hay, a certain quantity of urine, and a mixture of beef-juice and egg-albumen. The three mixtures were made in definite proportions, set aside for a certain time and examined microscopically. Where motion or life was perceived, the substances were added in larger proportion or conversely, and “the process repeated till a point was gained where none or only the faintest movement was perceptible.” Then the strength of the solution was ascertained and its preventive power noted.” To secure exactness, the experiments were afterward repeated. It was decided that “amongst the organic acids the ‘benzoic’ is first in average, though third in the albumen column. This substance, it appears, has not received the attention it merits. No doubt gum benzoïn has long been used in the preparation of fumigating pastilles to overcome unpleasant odors, but the general impression is that these are merely masked, not destroyed. The results of the experiments, however, indicate something more than this; because, although the albuminoid preventive point of picric acid is much higher than that of ‘benzoic,’ and though that of carbolic acid equals it, still it has an average greater than the former, and double that of the latter. Its mode of action is not clear; probably it is assisted by the small quantity of empyreumatic oil always present in its commercial crystals.”

No doubt benzoate of soda has been employed in this country against diphtheria. The prominence given to it by your journal will develop new facts with regard to its antizymotic properties.

Respectfully,
F. A. BURRALL, M.D.

48 WEST SEVENTEENTH STREET.

“STATE MEDICINE.”

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—If your Washington correspondent, Dr. Reburn, will read my essay with sufficient care, he will find that, while the adoption of the principles there advocated may serve to curtail the display of a certain amount of superfluous official energy, they will, nevertheless, confer upon sanitary authorities all the power which is needful for the proper management of disease in its relations to public health. No one denies the right of the State to guard the equal rights of all its citizens. If we then admit, for the sake of argument, that the domestic epidemic diseases are injurious to the community, there can be no doubt that the authority of the government should be exercised to keep people from spreading infection through the highways and public places which are intrusted to the care of the central power. But, beyond this, that authority cannot proceed without flagrant injustice. It cannot enter the home of a citizen, and command him to order it thus and so, without unjustly abridging his right to use his property as he pleases within his own private sphere. To use the comparison employed by the doctor, the police authority has a right to prevent a man from making a bonfire of his house, because he would endanger the safety of other houses;

* London: J. & A. Churchill, New Burlington Street. MDCCCLXXI.

but no power has any right to prevent that man from burning his house piecemeal in his stove, if poverty or his peculiar whims incline him to make such an end of his property. In like manner, the government cannot justly interfere with the legitimate business of a citizen, for the sake of preventing the spread of disease, unless it makes compensation for all direct losses which may be thus occasioned; for it is a well established principle of social science that the State cannot, without injustice, take from the citizen more than it returns to him. When, therefore, a sanitary official destroys the business and the income of a family for the sake of other citizens who have no claim upon them, and makes no compensation for the loss, he is guilty of the grossest injustice.

Such are some of the reasons which make it wrong for sanitary authorities to cross the line which separates the private life of the citizen from his public relations. Many others suggest themselves to the thoughtful mind, but I will not unduly occupy your space by their recital. As for the measures of compulsion which may be justly employed by the State within its legitimate sphere, the relations which exist between the public life and the private life of citizens are so numerous and so delicate that it is seldom expedient for the State to intervene in the management of domestic epidemics. The reasons of this are founded upon experience, and have their origin in the constitution of human nature. Experience shows that when the central authority has provided means for the preservation of order and the maintenance of justice, the unimpeded energies of the individual units of society will secure for themselves all that is attainable by the community. But when a government undertakes to "stamp out evil"—whether moral or physical, it matters not—it invariably fails to accomplish its purpose; or, if it seems for a time to be successful, its success is purchased by the creation of evils which are often worse than those which were destroyed. Witness the experience of France when she eradicated Protestantism, and by the same act well nigh destroyed the industries and the moral sense of the nation. Witness the outcome of all attempts to destroy foreign trade by prohibiting duties, impoverishing the nation and creating an irrepressible system of smuggling. Witness the ruin of a flourishing export trade in live cattle, through the folly of a single ignorant health officer at the Chicago stock-yards. Witness the utter failure of the attempt to suppress scarlet fever by the enforcement of methods against which the British Medical Association has entered its deliberate protest—methods which actually set a premium on the concealment and unsuspected propagation of disease. Free trade in religion, in merchandise, and in health, will always yield the highest results that are conceivable. The accuracy of the parallel—Dr. Reyburn to the contrary notwithstanding—between the relations of the State to the religious welfare of its citizens and its relations to their bodily health has not escaped the notice of philosophers. It is Herbert Spencer who declares (*Social Statics*, p. 408) that "there is a manifest analogy between committing to government guardianship the physical health of the people, and committing to it their moral health. The two proceedings are equally reasonable, may be defended by similar arguments, and must stand or fall together. If the welfare of men's souls can be fitly dealt with by acts of parliament, why then the welfare of their bodies can be fitly dealt with likewise. He who thinks the State commissioned to administer spiritual remedies, may consistently think that it should administer material

ones. The disinfecting of society from vice may naturally be quoted as a precedent for disinfecting it from pestilence. Purifying the hearts of men from noxious vapors may be held quite as legitimate as purifying their moral atmosphere. The fear that false doctrines may be instilled by unauthorized preachers, has its analogue in the fear that unauthorized practitioners may give deleterious medicines or advice. And the persecutions once committed to prevent the one evil countenance the penalties used to put down the other. Contrariwise, the arguments employed by the dissenter to show that the moral sanity of the people is not a matter for state superintendence, are applicable, with a slight change of terms, to their physical sanity also." It was once thought wise and proper for the State to compel uniformity of belief in matters of religion. But the result was rebellion, secession, hatred of religion. The same result will follow similar compulsory efforts in behalf of health on the part of sanitary officials. If they will limit their functions in accordance with the principles advocated in my previous essay, there need be no doubt "that intelligent citizens, as a class, (will) submit to reasonable regulations, and even restrictions for the sake of the common good." But if these officials, as a class, go on as some of them have commenced, it will not be very long before there will be evolved among "intelligent citizens" a feeling towards sanitary administration which will need but little to ripen into something closely akin to contempt.

HENRY M. LYMAN.

CHICAGO, ILLS., Nov. 28, 1879.

PROPRIETARY AND TRADE-MARKED ARTICLES, OR NOSTRUMS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—"Pharmacopœia" is infinitely obliged to Julius Fehr for his strictures about patented and trade-marked articles. I was always under the impression that Chlorodyne, Winslow's Soothing Syrup, Tamar Indien, and Grains de Santé were patented as far as the English, French, and American laws permitted. A trade-mark is a partial patent at least, and often a very complete one as far as the results go. But leaving this quibble on his part, I will proceed to the more important and serious side of the question. All these articles are proprietary, and hence nostrums, for nostrum is derived from *noster*, ours, and merely means personal possession to the exclusion of others. The rules of the American Medical Association, of the State Medical Society, and of all New York County Medical Societies, discourage the use of these more or less secret and exclusive remedies, and absolutely forbid regular and honorable physicians from giving certificates for them. A *nostrum* is not necessarily a secret or quack medicine, although it generally is; but it is always a proprietary article, and often a partially patented or trade-marked substance, and occasionally a completely patented one. The publication of the formula does not relieve it from its proprietary or nostral character, for this is merely the specification of the contents. The mode of combination is generally, if not always, kept secret, and there is always some mystery or secrecy about the matter. I even hold that a certificate by physicians for a patented rubber-cushioned axle is out of order. For all these certificates, although given originally for publication in medical journals only, are always or nearly always reproduced in secular journals and even newspapers, and in handbills and circulars to lay persons, which

are often sent about in the mails, and even thrown broadcast into door- and cellar-ways, to the infinite degradation of the medical profession.

A patent, according to Webster, is merely a writing given by the proper authority and duly authenticated, granting a privilege to some person or persons. Patent comes from *patere* to open, and letters-patent are merely those which are open to the perusal of all, but conferring franchises, etc.

PHARMACOPŒIA.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 30th to December 6th, 1879.

BROWN, H. E., Capt. and Asst. Surgeon. When relieved by Asst. Surgeon Middleton, to report to the Comd'g Officer, Ft. Duncan, Texas, as Post Surgeon. S. O. 252, C. S., Dept. of Texas.

TAYLOR, M. K., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to go beyond limits of the Department, and apply for an extension of one month. S. O. 251, Dept. of Texas, Nov. 28, 1879.

CLEARY, P. J. A., Capt. and Asst. Surgeon. To report in person to the Comd'g General, Dept. of the East, for assignment to duty. S. O. 271, A. G. O., Dec. 2, 1879.

MIDDLETON, P., Capt. and Asst. Surgeon. Assigned to duty as Post Surgeon at Post of San Antonio, Tex., and to relieve Asst. Surgeon M. K. Taylor, as attending Surgeon at Dept. Hdqrs. S. O. 252, Dept. of Texas, Nov. 29, 1879.

CARVALLO, C., Capt. and Asst. Surgeon. To accompany troops ordered from Rawlins to Ft. Laramie, Wyo. T., and there take post. S. O. 109, Dept. of the Platte, Nov. 29, 1879.

ELBREY, F. W., Capt. and Asst. Surgeon. Assigned to duty at Ft. Bayard, N. Mex. S. O. 238, Dept. of the Missouri, Nov. 28, 1879.

HOFF, J. V. R., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to apply for an extension of two months. S. O. 270, A. G. O., Dec. 1, 1879.

COMEGYS, E. T., 1st Lieut. and Asst. Surgeon. When relieved by Asst. Surgeon Brown, to report as Post Surgeon to the Comd'g Officer, Post of San Diego, Texas. S. O. 252, C. S., Dept. of Texas.

APPEL, D. M., 1st Lieut. and Asst. Surgeon. Granted leave of absence for one month, with permission to apply for one month's extension. S. O. 241, Dept. of the Missouri, Dec. 2, 1879.

SMITH, R. E., 1st Lieut. and Asst. Surgeon. His resignation accepted by the President, to take effect April 1st, 1880. S. O. 271, C. S., A. G. O.

QUARANTINE AT NEW ORLEANS.—A meeting of the Citizens' Auxiliary Sanitary Association was held at New Orleans, December 1st. The object of the meeting was to forward the project of establishing a central quarantine station at New Orleans, under the control of the National Board of Health. As the establishment of such a station was opposed by the State Board of Health, that body was only represented at the meeting by one member. A resolution was passed recommending the proposed plan of a quarantine station on Ship Island.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending December 6, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarle Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Nov. 29, 1879...	0	4	56	3	96	62	0	0
Dec. 6, 1879...	0	8	48	1	122	51	0	0

THE LONDON LANCET AND THE CONTROVERSY ON SPASMODIC STRICTURE.—In a recent number of the *Lancet* (Oct. 18th) is a notice of the discussion between Drs. Otis and Sands concerning spasmodic stricture of the urethra. The editor of the *Lancet*, in the course of his remarks, takes occasion to throw out the insinuation that the statements of Dr. Otis are unreliable. We are much surprised at this, as the gentleman in question is considered at home to be thoroughly trustworthy. Dr. Sands has come to the rescue in a timely and effective note, which appears in the last issue (Nov. 22d), and which explains the reasons for the apparent misapprehension on the part of the *Lancet*. This, coming as it does from the other party in the controversy, is in exceedingly good taste, and relieves Dr. Otis from any possible imputation as conveyed in the columns of that journal. It would have been more in keeping with the British ideas of justice for the editor of the *Lancet* to have followed the example of Dr. Sands in this matter.

THE CLIMATE OF TEXAS.—Dr. D. B. Messinger, of Wilson Co., Texas, writes: "After a residence of seven years in West Texas, I find it remarkably beneficial to chronic invalids coming here from other States. This is accounted for by the mildness of the climate, the dryness and purity of the atmosphere, and the extraordinary number of pleasant days during the year, enabling one to have out-door exercise or recreation almost uninterruptedly. For the benefit of those who may not have the time or strength to look up the most salubrious points, I will suggest the centre of the Oak Openings or timber belt, about forty miles below the mountain region and Wilson County, combines advantages not found elsewhere, having plenty of game for the sportsman in its forest and fish in its rivers, numerous medicinal springs of tonic and alterative waters, some peculiarly beneficial to consumptives. Chronic invalids are cured or relieved by a winter's sojourn in this salubrious region, which is undoubtedly one of the best in the United States for cases of phthisis, bronchitis, asthma, catarrh, rheumatism, and dyspeptic conditions."

DR. ALEXANDER MACALISTER has recently been elected to the chair of Anatomy and Surgery in the University of Dublin.

TYPHOID FEVER.—Sir Wm. Jenner has recently delivered an address on the "Treatment of Typhoid Fever." The question of the contagiousness of this disease has been thought of so much popular interest, that it has been discussed by Dr. T. Macalister in the November issue of the *Nineteenth Century*.

PROFESSOR ERASMUS WILSON.—A munificent offer has been made by Mr. Erasmus Wilson to erect for the Margate Sea-bathing Infirmary a new wing, with wards for seventy patients, a tepid swimming-bath, and a chapel. The total cost will be over \$100,000.

THE NEW ANÆSTHETIC.—M. Paul Bert's gaseous mixture—nitrous oxide and oxygen, under pressure—is now being used in two Paris hospitals. It has been administered in cases lasting over an hour.—*British Medical Journal.*

MEDICAL STUDENTS.—There are 5,231 medical students in the twenty-four larger German universities. The number of medical students in the nineteen English medical colleges was, up to October 29th, 898. In the United States there are between sixty and seventy regular schools. The number of students is between eight and nine thousand.

VIRGINIA STATE MEDICAL SOCIETY.—This Society held its Tenth Annual Meeting at Alexandria, Va., November 21st and 22d, Dr. L. S. Joynes, the President, being in the chair. Dr. Oscar Wiley and President Joynes delivered annual addresses.

The question of investigating the mineral waters of the State was discussed, and referred to committees. The project of forming a Medical Aid Society was also favorably discussed, and referred to a committee.

The following officers were elected for the ensuing year: President, Dr. Henry Latham, of Lynchburg; six Vice-Presidents: Drs. W. H. Bramlett, R. C. Powell, G. K. Robinson, W. P. McGuire, W. W. Daughtry, C. C. Conway. Treasurer, Dr. L. B. Edwards. Secretary, Dr. Charles S. Britton.—*Southern Clinic.*

ST. JOHN'S GUILD.—At the recent meeting of the Board of Trustees of this Guild, Rev. John W. Kramer, D.D., was elected Master.

DIRECTORY FOR NURSES.—A Directory for nurses has recently been opened in the Medical Library Building at Boston. It is under the management of three experienced ladies and two active physicians. It is intended to have here a full registry of the names and residences of nurses, with a statement of their engagements, and especial qualifications. Applications from the country by letter or telegram will be attended to. Already sixty or more nurses have registered, and the plan has every prospect of success.—*Bost. Med. and Surg. Journ.*

MASSACHUSETTS HEALTH BOARD.—This board has recently sent out a circular letter to all the physicians in the State, requesting replies to a series of questions upon sanitary matters.

A SANITARY CONVENTION AND EXHIBITION.—The Michigan Board of Health has undertaken to get up a sanitary convention and exhibition, and has sent around circulars of invitation to medical men and sanitarians both at home and abroad. The proposed meeting will be in Detroit, Jan. 7, 1880, and will continue for two days. Papers will be read on the following subjects: The "Abattoirs of Cities," "School Hygiene," "Ventilation of Living and Sleeping Rooms," "Cooking Schools," "Plumbing for Dwellings," "Prevention and Limitation of Contagious Diseases," "Inspection of Food," and "Water Supply to the Family." One feature of the convention will be the exhibition of sanitary appliances, or of models, drawings, and photographs thereof, when too bulky for transportation—the Board of Health reserving the right to decline articles deemed un-

suitable. These will be examined by competent judges, and certificates of merit awarded. The convention is thus officered: President—Ex-Gov. H. P. Baldwin. Vice-Presidents—the Hon. James Birney, William Brodie, M.D., the Hon. W. L. Webber, Prof. J. M. B. Sill, Mrs. J. J. Bugley, Mrs. Morse Stewart. Secretary—C. C. Yemans, M.D., No. 84 Lafayette Avenue, Detroit.

HONORS TO DR. LEWIS A. SAYRE.—At the annual meeting of the Dutch Society of Natural and Medical Science, held in Amsterdam, November 5, 1879, our countryman, Dr. Lewis A. Sayre, was made an honorary member.

A PUBLIC *concours* for the position of Lecturer on Gynecology in Rush College, Chicago, is to be held on the evening of Jan. 6, 1880. Candidates will lecture before the faculty and class on subjects previously assigned them. Applications will be received by the secretary from any part of the country.

THE STAFF OF THE PENNSYLVANIA HOSPITAL, PHILADELPHIA.—Dr. MORRIS Longstreth was elected, at the last meeting of the Board of Managers of the Pennsylvania Hospital, successor to Prof. J. Aitken Meigs, whose death caused a vacancy in the staff of visiting physicians to the hospital. Dr. Longstreth has been pathologist to the hospital for a number of years past.

OBSTETRICAL PRACTICES AMONG THE JAPANESE.—After pretending to reduce an assumed irregular presentation by abdominal manipulations, the medical man makes the patient stand up and put her arms around his neck. He then braces his shoulder against her breast, and presses his knees up between hers, in such a manner that she is firmly supported. While in this position, he practises a lateral massage with his hands, beginning at the seventh cervical vertebra and rubbing downward and forward, snapping his fingers all the time to distract the attention of the woman. Finally, he rubs the nates and hips with the palms of the hands from behind forward, beginning at the sacrum, and repeating the movements from sixty to seventy times. This process is repeated every morning after the fifth month.

It is scarcely necessary to add that the practising *accoucheurs* in Japan are, as a rule, advanced in age.—*La France Médicale.*

THE LATE DR. OLIVER WHITE bequeathed his library and one thousand dollars to the Presbyterian Hospital of this city, five hundred dollars to the New York Academy of Medicine, and five hundred dollars to the Society for the Relief of Widows and Orphans of Medical Men; and the late Dr. Freeman J. Burnstead also willed his entire medical library to the New York Academy of Medicine.

DR. VALLET, of Orleans, France, died in that city on the 1st of November, at the age of 85 years. He had been a practising physician for the unusually long period of 61 years. He was formerly chief surgeon of the Hôtel-Dieu of Orleans, and was a corresponding member of the *Académie de Médecine*, and of the *Société de Chirurgie* of Paris.

SOUTH-EAST MISSOURI MEDICAL SOCIETY.—This society, at its annual meeting held November 9th and 10th, passed, by unanimous vote, the following resolutions:

Resolved, That the South-east Missouri Medical Association cordially endorses the action of Harvard Medical College, Bellevue Hospital Medical College, Medical Department of Yale College, Medical Depart-

ment of University of Pennsylvania, Georgetown Medical College, and the Chicago Medical College, in their endeavors to elevate the standard of medical education by making a preliminary examination and a three-year course the requisite to graduation.

Resolved, That no member of this Association should receive any student unless said student first pledges himself not to enter any medical college in the United States, except those requiring a preliminary examination and a three-year course of graded instruction.

The Society elected Dr. E. A. Simpson, President, and Dr. A. A. Bondurant, Secretary, for the ensuing year. Its next meeting will be at Commerce, the first Tuesday in May, 1880.

At the close of its regular proceedings, a grand banquet and ball was tendered the visitors by the profession in Cape Girardeau. This was a very successful and happy affair.

DR. WALTON H. PECKHAM.—Dr. Peckham died at his residence in this city, December 6th. He had for a long time given up the practice of medicine, and had been engaged in business pursuits.

FIRE AT BELLEVUE HOSPITAL.—On the night of December 6th, a pavilion ward at Bellevue Hospital caught fire and was burned nearly to the ground. There were twenty-nine patients in the ward, part of them children. The pavilion was of wood, and burned so rapidly that three children were lost in the flames.

The building was known as Ward 31. When first put up it was devoted to cases of erysipelas, bad burns, cancers, etc. It being too near the hospital building for such purpose, another pavilion for these cases was put up, and Ward 31 was devoted to children and women. It was not a suitable structure for a hospital ward, and had already been condemned by the commissioners. A brick building will soon be erected to replace the burnt one.

THE PLAGUE IN RUSSIA.—The German commission, consisting of Drs. Hirsch and Summerbrodt, sent to Astrachan to study the Russian plague, have returned and made their report. This report gives a history of the disease and of the epidemic as complete as it could be made. Nothing especially new or valuable, however, was brought back, as the commission did not see any cases personally, and had to get information second-hand.

TRAINED NURSES.—A very instructive address was recently delivered before the Washington Training-School for Nurses, by Dr. Jos. Taber Johnson. A history of the origin of training-schools in this country is given. It shows how slow and hard the work has been to furnish the public with something of which it is in urgent need.

Nurses first received practical instruction in the hospitals of Philadelphia. It was in New York, however, that the first regularly organized school was established with all the necessary arrangements for systematic training. This was at Bellevue Hospital. The second school was opened in Boston, Nov., 1873; the third in New Haven. There are now schools in a number of the large cities. The value of such schools has been thoroughly appreciated, and their success has in most cases been rapid and complete.

The career of a trained nurse opens up a new field for young women. It is a life which has many pleasant features, in spite of the labor and responsibility it exacts. A good trained nurse is now heartily appreciated by the physician, and rarely fails to earn the good-will and gratitude of the patient.

The pay of trained nurses is generally better than that given to the same class of women in any other branch of work. From \$10 to \$20 a week are the limits generally.

The Training-School for Nurses at Washington seems to have had many difficulties to meet. This was due to the fact that the largest hospital in the city is in the hands of the Catholic Sisters of Charity. Provision has, however, been made for instruction at the Columbia and Freedmen's Hospitals, and it is probable that the school will now become prosperous.

The supply of trained nurses in most places is lamentably small, and it is to be hoped that efforts to increase the number will be successful.

CHOLERA IN JAPAN.—Dr. D. B. Simmons, of Yokohama, writes: The cholera epidemic which has been raging during the summer from one end of the empire to the other is rapidly abating. In Yokohama there have been but two cases the last ten days. In Tokio the number is also greatly reduced, not more than two or three cases being daily reported. Total number of cases for all Japan, up to Oct. 25, 156,734. Deaths, 90,627.

ROTTEN TEA.—The *London Times* announces that rotten tea, the refuse of importations of 1871 and 1872, colored with greenish paint, is being sold in London. As no place gets far ahead of New York in the matter of adulterations, we can reasonably expect some of the same among us very soon.

MENTHOL AS AN ANTI-NEURALGIC.—Some additional testimony to the value of menthol in sciatica has been sent to the *Lancet*. In three cases all were relieved for a time, and one notably so. The solution used was a weak one (gr. j. to ℥ xx. of rectified spirits).

DR. THOS. KENNARD died at St. Louis, Nov. 9th. He was ex-president of the St. Louis Medical Society, and had long been a prominent man in the profession.

MEDICAL OFFICE IN INDIA.—The position of principal medical officer in India, now held by Surgeon-General J. H. H. Innes, C.B., is to be vacated. The successor will probably be Surgeon-General T. Crawford, M.D.

PRISON EPIDEMICS.—According to the *Louisville Medical News*, 289 prisoners in the penitentiary at Frankfort are down with the diarrhoea. A communication between the drains and the water-supply is supposed to have been the cause. The Kentucky Penitentiary is said to be in a very filthy state.

Original Lectures.

CLINICAL LECTURE ON

DEMENTIA, IDIOCY, IMBECILITY;

BEING THE THIRD OF A COURSE OF FOUR CLINICAL LECTURES UPON THE DIAGNOSIS OF INSANITY,

DELIVERED AT THE NEW YORK CITY ASYLUM FOR THE INSANE, WARD'S ISLAND.

By A. E. MACDONALD, M.D.,

MEDICAL SUPERINTENDENT.

GENTLEMEN:—The mental conditions which we are to study to-day differ essentially from those which have engaged our attention at our former meetings. Then we were confronted by minds which had lost none of their normal activity, which were, if anything, more than normally active, and which found their difference from ordinary sane minds in the abnormal manners and channels in which their activity was manifested. The common phrase by which an insane person's condition is expressed—that he has "lost his mind"—could not, with propriety, therefore, be applied to the victim of either mania or melancholia; for there is disturbance, not loss. But, as applied to the sufferer from dementia, and only when so applied, the term is a proper one. As regards imbecility and idiocy, they have this in common with dementia, that in each of the three conditions there is deficiency of mind; but in their case the deficiency is an original one, while in dementia it is acquired. Hence, it is customary to group them under the designation "amentia," so marking the essential point of distinction between them and dementia.

Dementia, then, to begin with, is that form of insanity in which we find not merely distortion or misdirection of mind, but actual deprivation of it. In the patients before you, you see a very different condition of affairs, both mentally and physically, from that which marked those who occupied their seats at either of your previous visits. You find a dull, stolid, heavy countenance, a fixed attitude, and an utter failure to respond to external influences, or to indicate in any way that the patient is conscious of his surroundings. Before—in the one instance, as part of the general excitement; in the other, from fear or suspicion as to their possible bearing upon them—the patients manifested a lively and anxious interest in our movements and our words. Now the eyes and the ears of our patients seem to take cognizance of neither the one nor the other.

Of dementia, as of the other forms of insanity which we have already considered, different divisions are made by different authors and teachers. Some speak of the disease as either acute or chronic, while others recognize primary and secondary dementia as constituting its two forms. The first classification I consider undesirable, for, whatever its origin or duration, there is at no time anything *acute* in the symptoms of the disease; and I prefer to adopt, and to recommend to you the adoption of the latter. By secondary dementia we mean that form in which the disease comes on as a consequent or terminal condition in the course of an attack of insanity of one or other of the types which we have already considered,

or after apoplexy or epilepsy, or some other nervous disease; or yet, again, in the general decay of the vital powers which attends advancing age. By primary dementia we understand the form in which the insanity possesses the characteristics of dementia from the outset. Of the two, secondary dementia is relatively of very much more frequent occurrence, primary dementia being met with comparatively rarely.

We have already spoken of the approximation of the different forms of insanity, one toward the other, and of the mixed and doubtful cases which occupied the border-line between each; and in the case of mania and melancholia we found that by no means all the patients showed only the typical evidences of one or the other form, but that in many they were so mingled or so alternated that it was sometimes hard to say to just which side the patient belonged. Similarly, in dementia, there is an approach toward its next neighbor, melancholia; and primary dementia and melancholia with stupor, have much in common in their symptoms. In a general way, we may usually differentiate upon the grounds that melancholia with stupor is found in older persons, and that there are emaciation, refusal of food, want of sleep, suicidal tendencies, which are not met with in dementia.

CASE 1.—Here is a young man whose disease takes the form of primary dementia, and whose attack commenced at about the average age of patients so attacked—in his twentieth year. The victims of primary dementia are all young, ranging from fifteen years upward, and they are generally of weak constitution—boys and girls who have outgrown their strength, as the saying is. In some instances the attack comes on very suddenly, and then it usually owns a moral cause. Sudden fright is the most common, and the patient is literally frightened out of his wits. From this form recovery is more likely to occur than from that of which we shall presently speak, and from which the patient before you suffers. Girls are, perhaps, more frequently than boys, the victims of the suddenly developed form; and coincident with it, and lasting as long as it continues, there is then suppression of the menstrual function. There seems to be complete prostration and stagnation of the bodily and mental functions; the circulation is depressed, and the extremities cold and congested; there are constipation and retention of urine, and general relaxation of the muscles, so that the patient sits in a listless and stooping position. The mind seems closed to all external impressions, and there is, after recovery, if that takes place, no recollection whatever of what has happened during the continuance of the disease. This period is a perfect blank to the patient, who cannot even judge as to its extent; whereas, after recovery from other forms of insanity, the patients have usually a tolerably clear remembrance of what was said and done in their presence, even at times when they appeared to pay the least attention and to be the least capable of understanding. Refusal of food is common in the cases of which we are speaking—or, I should say, rather neglect of it. The patient will not feed himself, nor even convey the food to his mouth if it is placed upon the table before him; but there is not active resistance to feeding, and if food be placed in the mouth it will be swallowed mechanically.

But, as we have said, primary dementia oftener approaches in a different way, and has different characteristics, as in the case of this boy. Here the approach was gradual; there was a recognizable period of change, and there are two points in the history

which may always be pretty confidently looked for when the approach is thus gradual. These are hereditary predisposition and self-abuse. We have learned regarding him that his father and two sisters have been of unsound mind, and that he was himself a masturbator. This is the common—in fact, the almost invariable history in such cases. The children have been considered uncommonly bright and studious, and it is quite usual for the parents to boast of this fact, and tell how they would spend hours alone over their books; the suggestion that the solitude was perhaps sought for another purpose being always indignantly rejected. And this leads me to speak of masturbation as a factor in the production of insanity, and of the undue importance that has at times been assigned to it. There is a good deal of fashion in this matter of the assigned causes of insanity; sometimes one ostensible cause is taken into favor, sometimes another, and masturbation has had its turn with the rest. Not many years ago it was gravely asserted that a fabulous percentage—75 or 80, I think—of the inmates of asylums owed their insanity to the practice of self-abuse, and this statement went the rounds of the press, and was duly turned to their own account by the venders of certain quack medicines. Such exaggerated claims are not now generally made, but still the efficiency of this particular cause is, in my judgment, greatly overrated by some. Apart from the special form of insanity of which we are now speaking, I doubt if masturbation is to blame for many cases, although we do find patients with other forms practising it. In these cases, however, it is far more likely that the insanity has preceded, and led to the habit, than the reverse. In the present instance, however, and in cases of this class, its potency cannot be doubted, and the existence of the habit, the gradual approach of the disease, and the hereditary taint, combine to mark the case as incurable.

CASE II.—Here is a fair type of secondary dementia. He is a man of forty-six, and has been about ten years in asylums. In his case the primary disease took the form of chronic mania, and you see the stiff wiry hair so often associated with that condition still remaining. He is fat and well-nourished, does not speak at all, has a foolish smile, and shows the interest of a child in bright colors and trinkets. This taking on of flesh usually attends the transition to secondary dementia from the more active forms of insanity. The delusions are lost, life becomes mechanical and automatic, and the patient becomes gradually more and more stupid, and passes down through the animal grades until his existence is more like that of a vegetable than anything else.

CASE III.—This man is a case of senile dementia. His loss of mind has not followed upon any other form of insanity, but has simply come on gradually as his years have gathered. He is seventy-eight years of age, and you see that he is childish and simple. He prattles away in a silly manner, is sometimes petulant and irascible, but, as a rule, gives very little trouble, and is easily controlled and directed. The prominent feature in these cases is loss of memory, and particularly as regards recent events. Occurrences which were impressed upon the mind in earlier days, when it had not lost its vigor, are remembered and detailed with considerable accuracy; but present happenings seem to make no impression, and are at once forgotten. For example, the senile dement will tell you very correctly some story of his early life, and a few hours afterward he will tell it to

you again, equally correctly, but quite forgetting that it is not new to you.

Of course, there is nothing to be done for such cases with any expectation of improvement; the only thing is to make them comfortable for the rest of their days, and this may generally be done at their homes. The physician's connection with them is more apt to be in the capacity of adviser upon the point of their ability to make wills or execute contracts. Then it will be well to remember that the law does not require a man performing such acts to be as strong of mind as he ever was, but only to be strong enough to appreciate the nature and the effect of his acts; and further, that in this, and indeed in all forms of insanity, there is occasionally, just before death, a temporary clearing up of the mind, which takes it back for the time almost to its former vigor.

CASE IV.—Among the synonyms for dementia sometimes used, is that of "cataleptoid insanity." Here is a case that illustrates the occasional appropriateness of the term. This man has sat immovable during all the time that I have occupied in introducing the other patients. His head is bent forward, his eyes fixed, his mouth open, with the saliva dribbling from it, and his arms hanging by his sides. When I take hold of his arm and urge him, he rises, and again becomes immovable. As I place my hand on his shoulder and push him, he steps out like a walking doll, and the moment I stop he stops, and there he will stand until he is moved again. Now I raise his arms and bend them in different positions, and they remain just as I place them. I bend one knee and raise his foot from the ground, and he stands steadily upon the other. I press him back into his seat, raise both feet in the air, and in that position he will remain until it is changed for him. This is an excellent example of what has been called the "lay-figure" condition, or the condition of "waxy mobility." Of course, this man does nothing for himself, but has to be attended to and moved about like a machine. Even if food were placed in his mouth, it would remain there unswallowed, and so he has to be fed with the stomach-tube. He has to be taken up and dressed and undressed and put to bed again; and he passes his dejections without heed, if he passes them at all. Often the bowels have to be relieved by injection, and the bladder with the catheter.

We pass now from the dements to the idiots and the imbeciles. Idiocy and imbecility are not properly forms of insanity, certainly not so under the definition which we agreed upon; for their difference from the normal condition cannot be determined by comparison of the individual suffering with himself at another time. In their case we are obliged to set up an ideal standard and judge their victims by it, and not by remembering their normal condition. They are, in fact, *in* their normal condition. With dementia they have this in common, that there is in each case want of mind; but in one case the want arises from loss, and in the other from original absence. Differing in this from dementia, they differ between themselves, idiocy being a congenital condition, and imbecility a condition of arrested development, the arrest occurring after birth, and at a longer or shorter interval. I do not mean to say that an idiot or an imbecile may not be insane. His brain may take on diseased action, and he may have an attack of acute mania or of insanity of some other form as well as another. But the existence of his idiocy or his imbecility does not in itself constitute insanity. In other words, he may be of defective mind without being of unsound mind.

The patients before you are not inmates of this Institution, but come from the Idiot Asylum on Randall's Island, by the kind permission of its superintendent, Dr. J. C. Howard. Among them are some idiots and some imbeciles, but in each one you will notice one or more defects in physical development which establish a decided contrast between not alone them and ordinary mortals, but between them and the insane persons who have already appeared before you. Taking the idiots first, you will notice a very decided difference between them—an anatomical one. Some of them have very small heads, some of them very large, and we divide them, therefore, into microcephalic and macrocephalic idiots. As a rule, the large-headed are, more properly speaking, imbeciles, for the brain is not simply undeveloped, but diseased; but this is not always so. The capacity of the skull does not always indicate the size of the brain; and the former may be very great, and the latter very small. In a general way we may say, that the brain of the idiot represents quality without quantity; while of that of the imbecile the reverse is the case. As a rule, the terms which we have used have fairly suggested their own definitions; but in the present instance I fear that this is scarcely the case. For in the original the term idiot meant one who had not sufficient intellect to engage in political affairs or hold political office; and in these later days there is a suspicion that it has somewhat lost its significance in that regard. Ancient tests also have, to some degree, lost their value; for one of those in best repute was, to require the alleged idiot to identify his own father and mother, while more recent authority has declared one-half of that to be difficult even for a wise man.

With these idiots I can do little beyond directing your attention to the physical peculiarities which they present. I know nothing of them myself as to their histories and so forth, and but little is known at the institution from which they come. How little, may be judged from the fact that one of them is known as "Central Park"—a name probably not acquired in the usual way from his godfathers and godmothers, but rather from the locality in which he was found; while a second is called "Sloppy," in delicate allusion to a personal characteristic which is sufficiently apparent to you.

CASE I.—This is an historical idiot, who has been described and pictured in more than one medical work. At first glance, you would take him for a little boy, but he is in reality about forty years old, and has been on Randall's Island nearly twenty years. You see that he is short and stunted in figure, with disproportionately long limbs, but his remarkably small head is his most striking feature. It is about equal in size to the two fists held together, has a circumference but little over half the average measurement, and is altogether as good a specimen of the microcephalic head as you are likely to see. When you look at it in profile, you see what a decided departure from the usual proportion of the length of the face to that of the entire skull there is. Here the face is of less than ordinary length, but the forehead and the top and back of the skull are so flattened and reduced that it appears to be of unusual length. This disproportion you find in the other cases also, but in less marked degree.

As to this man's parentage we are uninformed, and we are therefore left to conjecture as to the probable cause of his condition. The bones of his skull have the appearance of unusual firmness and thickness, and the sutures are firmly knit. It may be that their

premature ossification, and the failure of expansion of the calvarium exerted pressure upon the brain, and so prevented its growth. This is one of the assignable causes of idiocy and imbecility; others are heredity, and especially where there is blood relationship between the parents; intemperance or diseases in the parents (syphilis being particularly operative), and ante-natal impressions—fright to the mother during pregnancy, and the like. In the case of consanguinity of parents, there must, of course, be family defect, which becomes intensified by the breeding-in. That there is danger where no such defect exists is not proven, and not probable; of the potency of ante-natal impressions there is no decisive evidence. Diseases and intemperance of parents are, no doubt, the most usual causes in which they are concerned.

The amount of intellect possessed by this man is almost nil. I believe the repetition of the word "tobacco" forms the extent of his conversational powers. So you will fail to get many mental evidences of his condition. But of physical irregularities there is no lack either in him or in his companions. In almost every feature, one or another of them shows some departure from the usual, and you will observe that in these departures the tendency is toward the form of the lower animals—a point of interest to believers in the Darwinian theory. If we could remove their skull-caps and look at their brains, we should, no doubt, find them approaching that of the ape in organization. The convolutions would be simple and few in number, and those of the two sides symmetrical.

Externally the mouth and lips show unusual conditions, and so with the oral cavity. The lips are large and thick; hare-lip is common; and cleft palate often goes with it. The upper jaw is lengthened and narrowed, the roof of the mouth arched, and the teeth are irregular, deficient, and decayed. Often the incisors are pushed forward and detached from the others—markedly resembling their arrangement upon a separate bone, as in animals.

Defects in the eyes and their appendages are common. This man, as you see, is almost blind, and two of the others have strabismus.

The bodies, as a rule, are ill-developed. Some have club-feet, some hunchback, and so on. Here is a negro whose feet look as if they were formed to clutch the limb of a tree, and it does not require a great stretch of the imagination to picture his ancestors in no very remote generation, jumping or swinging from limb to limb of some African forest.

And with this return, if we may call it so, toward the appearance and form of other animals, there is an equally perceptible return in habit and action. The place of intellect seems to be supplied by instinct, and by it the behavior is apparently often governed. Thus, in a recorded case, an idiot girl having, while alone and unattended, given birth to a child, turned with the instinct of an animal and gnawed the umbilical cord. Commonly, there is a consistent imitation of the habits of some one animal, and its posture and movements will be assumed, and its habits copied even to the extent of showing a preference for whatever forms its natural food. I have read of a case where a woman lived and acted like a sheep, and ate grass; and I know of a case where a young man has all the habits, and a good deal of the appearance, of a well-conducted horse. He harnesses himself to a wagon every morning and trots about all day, switching a tail which he has fabricated out

of old rope; and so great is his consistency that he never fails to shy at sight of a wheelbarrow.

CASE II.—Here is an equally good specimen of the opposite condition, the macrocephalic. This boy's head is almost as big as his body, and is at least four times larger than the average. In appearance he is infantile, and in conduct, too; but I learn from the card sent with him that he is eighteen years old. Beyond this, we have no information. His head is so large and heavy that it falls upon his shoulder, unless supported. The sutures are unclosed—indeed widely separated; and there is fluctuation, which shows that the condition is not due entirely, if at all, to abnormal size of brain. The proportions observed in profile between the measurements of the face and skull are the reverse of those found in the last case; the face is now but a small proportion of the entire length.

CASE III.—Here is a young man who will give you a good idea of what constitutes an imbecile. There is nothing stunted about him, for he is very tall; but he is awkward and shuffling, and acts like an overgrown boy who hasn't learned what to do with his limbs yet. He has that general appearance, too; and when he speaks it is in a shrill treble, though his age is thirty-five. His face is smooth; there is no hair upon the nates; his sexual organs are infantile in size, and the testes are atrophied. He has some intelligence, but not a great deal; and his answers to questions are silly and incoherent. He has hare-lip, as you see, and the condition of the teeth of which I have spoken. When out of doors he runs about like a child; laughs and cries by turns with little or no cause; and he is very fond of chewing grass or leaves, or anything, even earth sometimes, that he can pick up.

Like other imbeciles, he was probably born with as good a brain as other children, and the arrest of development came afterward, and he has remained just what he was mentally when it came. Sometimes imbeciles are born unusually bright children, and go through the first years of life without any suspicion or apprehension of any defect; but finally the stopping-place is reached, and their companions pass them, and thereafter, to whatever age they may attain, they remain mentally undeveloped. Often, by way of compensation, some one talent or aptitude is possessed in an unusual degree. Blind Tom is a familiar instance of this in the case of musical talent, but more commonly mechanical pursuits are those for which the greater fitness is shown. A proper recognition of this fact, instead of obstinate endeavor to push weak-minded children on in studies for which they have not the requisite amount of intellect, would make the lives of many of them more comfortable and useful.

MEMPHIS.—The committee appointed to make a sanitary inspection of Memphis has made its report, concluding it with a number of recommendations. Amongst these is the advice to have all the houses in the city ventilated and chilled; to condemn and destroy a certain number of infected dwellings; to introduce a system of sewerage; to secure the enforcement of building regulations for all future constructions.

The report says that few places have better natural advantages for drainage than Memphis.

The work of inspection was under the direction of a special committee composed of Drs. J. S. Billings and R. W. Mitchell; Mr. W. H. H. Bengard, Geo. E. Waring, Jr., and Dr. C. F. Folsom. †

A CLINICAL LECTURE

ON A

CASE OF APOPLEXY, WITH A POST-MORTEM EXAMINATION.

DELIVERED AT THE PENNSYLVANIA HOSPITAL,

By J. M. DA COSTA, M.D.,

PROFESSOR OF MEDICINE AND OF CLINICAL MEDICINE IN JEFFERSON MEDICAL COLLEGE.

(Reported for THE MEDICAL RECORD.)

AIDED by Dr. Morris Longstreth, the pathologist to the hospital, I desire to show you the results of a very interesting and instructive *post-mortem examination*. I had hoped, indeed, to bring before you the man himself, but it was decreed otherwise. He died last night.

The case was one of overwhelming, fresh apoplexy. The patient had only been in the hospital two days. He had the very best and most energetic treatment that we could give him, but it was of no avail. The pressure of the clot upon the brain substance was too great for any human power to prevent or modify.

This is the man's history, so far as it was given to us: J. G., *æt.* 66, a cabinetmaker by trade, married. His mother had died of apoplexy, but the patient himself had had no previous attack of convulsions and no palsy, and had always been a very temperate man. He had, however, had considerable domestic trouble, and all the time it had been going on he had worked hard at his trade, so as to make both ends meet. The worry and work combined to depress him. This is all that they told us when they carried him into the wards unconscious, and it was, at best, a negative history; for, according to it, he had always enjoyed good health, were it not for an occasional attack of vertigo. Six months before we saw him his wife left him, and since that unfortunate event he has remained hard at work, alone, morose, and despondent, in his shop. On the day before his admission, that is on November 5th, he was found lying on the floor by his stove, which was red-hot. He had evidently struck his head, which was badly burnt, against it in the act of falling.

When found he was comatose, and his breathing was noisy. His head, face, and neck were deeply congested; his pupils were contracted, and his mouth was drawn toward the right side of his face. There was also left-sided hemiplegia. This was plainly present even when he was found. They brought him into the hospital still insensible, with pupils still contracted and with left-sided paralysis still marked.

The treatment before admission had consisted in the application of wet cups to the left side of the neck. This had so far rallied him that, after he was put to bed in the wards, he raised his right hand to his head and mumbled something about headache. There was considerable cephalic congestion even then existing; the veins of the neck and forehead were prominent and tortuous; the face was dark. The case looked like one of venous congestion. The pupils remained contracted, and responded but slowly to light; there was ptosis of the left eyelid. The mouth was still drawn to the right, and the left arm anæsthetic; at least he did not seem to be sensible to pricking it with a pin. There was complete paralysis of the left arm. (I am now giving you the results of the very careful examination which I myself made when I first saw him.) The left leg could

be very slightly moved. The reflex contractions on both sides were active when the soles of the feet were tickled. The muscles on the left side responded to the faradic current. The pulse was 100; respirations 20 to the minute; temperature 98. The first sound of the heart was very feeble.

The man remained in this condition; not, however, without active efforts on our part to rouse him. Eight ounces more of blood were taken from his head by leeches, with this end in view, but still there was no change for the better. His temperature gradually rose to 101, and delirium set in. He began to pick at the bed-clothes. He was thoroughly purged with croton oil, and iodide of potassium was given in large doses. A blister was applied to the nape of his neck, and the fluid extract of digitalis was given hypodermically; but it was all of no avail. It was but too evident to us all that the intra-cranial pressure was too great to be compatible with recovery. The poor fellow died at 9.30 P. M. on November 7th. All that day the resident physician noticed his breath coming shorter and shorter. Delirium was active all the while. Occasionally he moved the paralyzed leg, and the right arm and leg were moved freely.

Here are the specimens, and my friend, Dr. Longstreth, will explain to you the very interesting pathological conditions present.

(DR. LONGSTRETH—"You notice here, gentlemen, an enormous fresh clot which has broken into the brain substance at the anterior part and right side of the corpus striatum. The softening, following the formation of the clot, has opened a way into the ventricle and emptied the blood into the anterior horn. All the ventricles, in fact, are filled with bloody serum, and all the vessels are deeply congested. The coloring matter has escaped from the blood and colored the serum.

"Looking carefully at the base of the brain, to determine the cause of the apoplexy, all the vessels—the vertebral, carotids, and interior cerebral arteries—were all found to be atheromatous. I have no doubt that the microscope would show that all the capillaries round the clot had undergone fatty degeneration. (This was subsequently proved to be the case.) There is very marked softening of the brain in the immediate neighborhood of the clot, but there is no absolute change discoverable in distant parts of the brain substance—*i. e.*, the softening is only local, and not general.

"The clot itself reaches from the front part of the corpus striatum, two-thirds of the way back, through the optic thalamus, and follows the course of the upper layer of the fibres of the right crus. The cavity itself, formed by the clot, is probably large enough to hold a hen's egg.

"The heart is fatty, and shows atheromatous changes in its valves, mitral and aortic—not enough, however, to interfere with the functions of the organ.

"The liver is indurated; the kidneys slightly granular, but not otherwise diseased. There is no albumen to be discovered in the urine. The lungs are soft and congested. The blood is in a bad condition all over the body. The congestion is most marked on the left paralyzed side.")

You have thus heard and seen, gentlemen, all that Dr. Longstreth has to show and tell you. If you will examine the specimens yourselves after the lecture you will see the large clot and the general breaking down of the tissues.

There has been a very striking correspondence between the anatomical lesions and the symptoms

manifest during life. It was very evident to us, during life, that we were dealing with a large clot. This was proved to us (1) by the overwhelming character of the stroke; (2) by the completeness of the paralysis; (3) by the very marked and equally persistent contraction of the pupils; and (4) by the want of successful action of the remedies employed; in other words, by the obstinate continuance of the pressure symptoms, in spite of all and any treatment that experience and theory could dictate. It was not hard, I say, to decide that it was a clot with which we were dealing.

Nor, on the other hand, was it beyond our power to decide where the clot had been thrown out. The existence of such complete motor paralysis of the left side of the body pointed indisputably to one of the great motor areas of the brain, presumably to the corpus striatum and to a clot tearing up everything there, and probably extending into the optic thalamus. All these facts of diagnosis were confirmed by the *autopsy* which has just been related to you.

Again, it was not difficult during life, judging from the character of the pulse, the tortuousness of the arteries, and the feeble first sound of the heart, to determine upon the existence of an atheromatous condition of the arteries. This very atheroma of the arteries was undoubtedly the cause of the clot. All these points were nothing else than we had foretold, and so we do not find anything in these *post-mortem* appearances to surprise us.

It is needless for us to examine the symptoms any further, particularly as my time is short; but there are several points of great interest in the case which I wish to discuss with you this morning, *viz.*: (1) the fact that the leg was not so completely paralyzed as the arm; (2) the depression of the temperature at first and its subsequent rise with its significance; and (3) the question of treatment.

To begin, then, I say that the fact that, while the left arm and leg were both paralyzed, the leg was less paralyzed than the arm, suggests to my mind the discussion as to whether, according to the present state of physiological science, one would not have been led to suspect a lesion of the cortical substance, rather than of the corpus striatum and optic thalamus, as was demonstrated conclusively by the *autopsy* in this case.

It is scarcely necessary to discuss this proposition minutely, namely, given a case of sudden development of hemiplegia in which the arm is more affected than the leg, or *vice versa*, does it, of necessity, prove that the particular motor ganglia supplying that arm or leg are affected, or may it be that the lesion is central, as in the present instance?

Notwithstanding the ingenious and truly scientific studies which have been pursued of late years upon the localization of cerebral functions, we are as yet unable to say with certainty whether or not a lesion, which, like the present, paralyzes an arm more than the leg on the same side, may not after all be (as it has turned out to be here) central rather than cortical.

In this regard these specimens are, without doubt, full of interest, as proving that a central lesion affecting the corpus striatum and optic thalamus may yet give rise to a hemiplegia which implicates the arm much more markedly than the leg, or the reverse, while the light thus far thrown upon the subject would seem to point unquestionably to the cortex as the theoretical seat of the lesion. It all goes to show that the differential diagnosis of lesions implicating the central motor areas is not yet scientifically complete.

As regards the treatment, although you did not see the case during life, you, no doubt, remember that we cupped and leeches the patient, and purged him thoroughly, with but little success. When the heart began to flag, the fluid extract of digitalis was injected hypodermically, without any permanent effect. There was not even so much as a temporary improvement. Even in the case of the digitalis, which elicits a response from the heart in every instance in which the heart is capable of responding, the results were entirely nugatory, and so, I fear, they always will be when the clot thrown out is so extensive. We could not have treated the patient otherwise or with any better effect than we did.

My rule in all cases of apoplexy is to draw blood at once; but when there is marked degeneration of the walls of the arteries, such as we find here, I have never had any striking results from this withdrawal of the pressure upon the brain. On the contrary, where the patient's circulatory system has been weakened from general atheroma, my experience has invariably been that he soon dies, either from exhaustion, or from a fresh breakage of the wall of some artery in the brain.

In concluding my remarks upon this very interesting case, I want to call your attention to the use of digitalis hypodermically for the purpose of sustaining a flagging heart. Two drops of the fluid extract are equivalent in strength to fifteen minims of the tincture. This amount (gtt. ij.), well diluted with water, is what I generally use, and I have always found that it answers all the purposes of hypodermic medication excellently. This dose can, of course, be repeated as often as necessary.

The patient's temperature record was a very significant one. The low temperature during the early part of the attack, and its subsequent rapid rise, indicated the existence of an irritative fever set up in the brain by the presence of the clot.

TARSAL OSTEITIS—EXCISION vs. EVIDEMENT.

By Prof. W. W. DAWSON, M.D.,

OHIO MEDICAL COLLEGE, CINCINNATI, OHIO.

THIS, gentlemen, is a case of osteitis, but for repair or recovery occupies a very unfavorable position. It involves, as you see, the tarsal region. There has been a well-defined slough of the soft parts leading down directly to the bone, and involves, from its position, I should infer, the scaphoid. The disease seems indeed to be confined to this single bone. It is osteo-periosteomedullitis, an affection of all the structures of the bone—the external crust, the cancellous portion, and the medullary matter.

When inflammation attacks a spongy bone, it is next to impossible to remove it. Nature seems to have no power to relieve bone of such structure. When, however, it attacks a long bone—a hard bone—the repair is made by an external slough, or by the destruction of the shaft. If the disease is confined to the periphery, a part of the shaft is strangulated and thrown off as a necrotic mass. Repair by granulation occurs beneath. A large portion of the bone may be lost, but it is so reinforced by new material, that the utility of the limb is not destroyed. When the whole bone is involved, and from the intensity of the inflammation it dies, then there is thrown around it a shell—a covering, a kind of shield. The bone may be completely necrosed in the interior, but this

new shell is sufficient for the weight of the body, if it be in the tibia or femur; or for prehension, if involving the humerus.

This process of destruction, repair, and compensation occurs, as I have said, in long bones; in solid or flat ones, like those of the cranium; but when osteitis involves the whole substance of a spongy bone, the action is continuously destructive, but not conservative—not tending to the restoration of the part. Inflammatory action progresses; molecular death follows proliferation; the diseased bone and new osseous deposits are thrown off in the shape of necrotic sand-osseous particles; and this process goes on month after month, year after year—an ever-open discharging fistula. This constant purulent discharge from bones leads often to degenerations of the kidneys, ending fatally.

If this should not occur, the patient is rendered more or less disabled by the influence of the ulcer, and must be subjected to the presence of an offensive discharge. The destruction of the kidneys is an evil of high grade—incomparably greater than the disability or the annoyance of an everlasting purulent discharge. Again, in cases of long standing, where the kidneys escape involvement, the system, subjected to a constant drain, grows pale and anæmic, the muscles become flabby, long-continued physical effort becomes impossible.

The disease, when the result of a trauma, is usually confined to the bone or bones originally injured. Fortunately, the osteitis does not extend from contiguity, from mere contact. Synovitis in the tarsus extends from continuity of surface—the synovial membranes are so intimately connected. As a rule, this is not the case when the bone structure is involved. Be careful here to make the distinction between osteitis, the result of an injury, and that arising from a vice in the system, such as syphilis or scrofula. The one is local, confined to the damaged bone; the other constitutional, and generally more than one bone is affected; or, if one alone be affected primarily, the affection will be transferred to others in the neighborhood. A few years ago I had a case which peculiarly illustrated this principle, as well as does the case before you. A bright little girl, the child of wealthy parents, was struck on the side of the foot with some hard body.

Osteitis of the tarsal bones in front of the astragalus followed. It was impossible to dislodge it. Counter-irritation, constitutional remedies, the trephine, and drainage, were all tried, but without result. Great suffering and positive disability attended the case. I then resorted to a radical operation; one that had been recommended by a Scotch surgeon; I removed the affected locality—that is, I disarticulated at the medio-tarsal articulation, and sawed off the metatarsal bones about midway between their upper and lower extremities, then dissecting the tissues from the sole and dorsum of the foot, the whole of the diseased neighborhood was excised and the foot shortened. The metatarsal bones were divided where they are essentially long bones, having a solid shaft traversed by a medullary cavity; these, at this point, have the ability to repair, after having been wounded or divided by the saw; in this instance granulations sprung up, and in a few weeks they, with the soft parts, had completely healed. To provide for the escape of necrotic fragments, I plugged the space left, after removing the mass, with lint, and allowed the restoration to proceed slowly.

She has a good foot—not symmetrical, of course; but it is a useful foot for all purposes. She dances,

A CASE OF
SUPPURATIVE PERITONITIS FOLLOW-
ING PELVIC PERITONITIS.*

By H. T. HANKS, M.D.,

NEW YORK.

runs, plays; and you would not be aware, if you were not told, from the movements of the child, that a surgical operation had been performed; it was a wonderful triumph.

I now present to you a lady with disease both of the scaphoid and also of the tibia. In the first it is osteitis; it has advanced to the stage of ulceration—molecular destruction—but the disease over the tibia involves only its covering that is thickened, enlarged, but has not reached the development of pus. It is a profitable opportunity to see the two forms, or rather the two stages of bone disease. In the scaphoid it has progressed until all the structures of the bone, as in the first case, are involved, and the destructive process still continues in the other locality; the covering of the bone is alone affected. The osteitis in the scaphoid seems to be local, confined to that bone, but the appearance of disease in the tibia leads us to suspect a dyscrasia—a constitutional affection.

Again, the fact stated by her physician, Dr. Albers—the marked influence of iodide of potassium over the affection—goes far to make the suspicion a certainty, that the disease may be specific. This fact excludes this person from the advantages to be derived from excision; that operation being alone suited to cases of traumatic osteitis, to an essentially local affection, to a disease with positive limits.

In the two cases associated—the child that had been operated on, and the female first presented—the local nature of the disease was without doubt. In the adult but one bone has been invaded, and in the child it was definite that the affection did not involve the bones behind the medio-tarsal articulation: there was in neither, constitutional or general implication of the system; hence, in the little girl, when the invaded section was excised, all trace of disability disappeared, and when the degenerated scaphoid is removed from this lady's foot she may expect a like result.

Some years ago Sedillot suggested the plan of *iridement*—the scooping-out of the interior of soft bones in cases of osteitis. He endeavored to leave the solid, thin exterior of the bone, with its periosteum, hoping for a reconstruction of the destroyed, broken-down bone. The osteogenetic process in the foot is slow and often unsatisfactory; in most instances I prefer excision.

For the relief of the second patient, surgery is almost impotent. The disease of the scaphoid is doubtless shared by the bones in its neighborhood, and we have already seen that the periosteum of the tibia is implicated; this will soon be transferred to the bone which it covers. Operative surgery, except to remove the debris—the products of inflammatory action in the shape of sloughs, or necrotic masses—is "meddlesome surgery;" it adds new life and gives activity to the disease which is slowly advancing.

There is, however, one remedy which exercises a marked influence over this form of bone disease. I allude to iodide of potassium. The drug, when given in from thirty to one hundred grain doses, three times a day, will be followed by striking results.

MEASLES IN NEW YORK.—Cases of measles have been increasing in frequency in this city during the past few weeks. From November 29th to December 6th, there were 126 cases reported; in the following week there were 171 cases. The disease prevails especially in the middle and western part of the city, and in some localities is quite malignant. In the week ending December 13th, there were twelve deaths reported.

On the 29th of July, 1879, I was requested by Col. M—, of Vermont, to see his daughter, a school-girl of fifteen years, who had been ill and confined to her bed since the early part of the previous April—nearly four months. From my friend, the colonel, I learned that his daughter had been under the care of Dr. M—, the village physician; that she was taken sick with symptoms, as the physician and the father supposed, of peritonitis. The disease, apparently, seemed to progress, until the whole abdomen was involved, and had so remained for several weeks. Then the swelling subsided, the pain diminished sufficiently to enable the patient to bear some slight pressure upon the abdomen. Her desire for food increased, her mind became clear, and both the physician and the colonel believed the crisis passed and convalescence begun. The father, who was exceedingly intelligent, watched his beloved daughter with untiring devotion. He noticed, after a short time, that the girl's lower limbs remained partially flexed, and that she was growing thinner and paler, notwithstanding the fact that food and stimulants were freely taken. A council of the neighboring physicians was called in May. In June, no improvement having taken place, Prof. C. and Dr. —, of Burlington, Vt., were summoned. The plan of treatment decided upon at these several consultations had been carefully carried out, but without favorable result. I should say here that I learned at this time that the daughter had been a constant attendant at school, an earnest, diligent student, and had led her class, which was large, and many of whom were very bright pupils. Also, that just before her illness, the family had moved into their new house, hardly dry from fresh plaster and recent paint, and that this circumstance might have been unfavorable at first.

The colonel's history of the case was confirmed by the physician in charge, who also stated that the girl had never menstruated; that the disease seemed to commence in the region of the right ovary; that it was ushered in, in the usual manner; that it had quickly spread until the whole abdomen was involved; that with opium, in different varieties, and local applications, the disease seemed to subside, after a somewhat *lengthy* course; but that tenderness over the abdomen had never entirely disappeared. He stated that there had been a rapid, feeble pulse (110 to 120) for the last two months; that the temperature had ranged from 100 to 101; that the appetite had improved, but that digestion had not been good, and assimilation was very imperfect. She had also vomited daily for the last two weeks previous to my visit, and that emaciation had continued. No distinct chill since first attack was ever noted by the attending physician, though she *may* have had a slight one. The physicians had all recommended tonics of different kinds, with stimulants and judi-

* Read before the Obstetric Section of the New York Academy of Medicine, Nov. 28, 1879.

cious diet. Prof. C. and Dr. —, of Burlington, had given a favorable prognosis, *provided* mesenteric consumption had not already begun.

At 9 A.M. on the 29th July, on coming into the presence of the patient, I found a young girl, apparently about fifteen, small for her age, with a bright, intelligent face, very pale, much emaciated, lying upon her back on the bed, with her thighs semi-flexed upon the body and legs semi-flexed upon the thighs; the voice was clear; she complained of inability to move her body or lower limbs, and of pain from any slight pressure upon the abdomen; could not allow her limbs to be straightened. She had no pain when left undisturbed, but even a *slight* jar of body, when being moved, occasioned great pain. Pulse was wiry, 120; temperature, 101°; respiration, 30°. Tongue slightly coated on the edges, and red in the centre. On gentle percussion, the parts being *exceedingly* sensitive, dulness was found to exist in region of right lower lung, in front. On auscultation, no healthy vesicular murmur was found in this immediate vicinity, but coarse, mucous râles existed in larger bronchial tubes. The mammae were as undeveloped as in a girl at ten years. The abdomen was flat, and muscular walls drawn tense, somewhat fuller than would be expected after so long an illness, which did not involve this region. There was no swelling, tumefaction, fluctuation, softening, or change of normal color anywhere discovered. The parts, however, being so exquisitely sensitive, an *absolutely thorough* and *deep* pressure examination was not made. By exercising great care in percussion, I was able to make out an increased area of dulness in right hypochondriac region, extending downward toward, and including right iliac region. The most sensitive spot seemed to be near the lower border of the liver. On auscultating the abdomen, the usual sound of the passage of air through the colon was less distinct than normal in this region, and in fact all parts of the lower abdomen; the mons veneris was destitute of hair; a vaginal or rectal examination was not insisted upon, believing that little could be learned in this case from either, since the patient was a small, delicate, and justly modest girl—and the symptom of the presence of pelvic cellulitis and peritonitis still existing in the drawing up of the limbs, the occasional distress and pain in the pelvis, especially in efforts at urinating and defecation, and the tense, painful condition of abdomen. The kidneys had been active, and nothing abnormal was found in the urine. The bowels moved two and three times a day of late. In the fecal matter, much undigested food was discovered. The patient had vomited the night before my visit, and, in fact, had vomited once or twice each day for a week. The food had been vomited soon after entering the stomach.

From these symptoms, as said above, I concluded that the patient had had a sharp attack of pelvic peritonitis, which had not even now fully resolved; that this condition had extended until there was general peritonitis, which still existed in more or less of a chronic state, and that within a short time a localized pneumonia had developed in the region of lower lobe of right lung. My prognosis was not hopeful; still, on my second visit, I expressed my belief that she might recover.

I advised a continuance of hypophosphites and stimulants in regular and moderate quantities; elix. iron, pepsin, and Peruvian bark, with regular and frequent use of a small quantity of milk and lime-water, with a little lamb chop or beefsteak, toast or rice. I ordered the abdomen in region of the liver, chest,

and lung of right side to be painted over with iodine faithfully once a day, with friction and massage to skin and muscles. I believe these recommendations were faithfully carried out.

I saw the patient again two days afterward (July 31st). Some symptoms were more favorable. Digestion better; had not vomited since previous visit; pulse, 115; temperature, 100½°; respiration, 24; limbs still flexed; abdomen still quite sensitive; appetite better; craves greater variety of food than she has been allowed; dulness over right lower lung certainly less marked; fewer mucous râles; no cough. From this time until the 9th of August there was but slight change. Digestion was better, and the respirations less frequent; but the patient grew more emaciated. Edema of the lower limbs manifested itself, and slowly extended upward. The fever seemed to increase every afternoon, and the temperature in the month would range from 101° to 103½° or more. The tenderness of the abdomen was so great, that a *thorough* examination by percussion and auscultation was at no time feasible. I was certain, however, that there was still an increased area of dulness over and below the right hypochondriac region. I expressed an opinion that there was an abscess of the liver, or at least near this organ. The patient was so feeble, and the prognosis so unfavorable, that both Dr. M. and myself feared the patient might not survive the exploration, and consequently the crucial test of the aspirating-needle was not made.

The following Wednesday (August 13th) the conditions had grown worse, and a sweetish odor to the breath was distinctly perceptible. Even then, for the same reason as before, the needle was not used. On the 17th the patient died.

On Monday, August 18th, an autopsy was held, at which Dr. M., Dr. D., and myself were present. The lungs and heart were found to be normal, except that there were traces of recent inflammation in the lower lobe of the right lung, and hypostatic congestion in posterior portion of both.

On opening abdomen, the stomach was found somewhat distended with gas, the liver enlarged, and its lower border, to the extent of nearly two inches, was embraced by the walls of an abscess which extended downward to the region of and involved right broad ligament. The front wall of the abscess was the peritoneum; the posterior, or floor of the abscess, was plastic lymph, which had completely agglutinated and covered the front of the intestines. The abscess extended inward to within two inches of the median line, and was about five inches long by three in width, and contained nearly a quart of pus. It was impossible to determine at what point the abscess began; but from the fact of its involving the right broad ligament, we may judge that here around the ovary was undoubtedly the *fons et origo* of the inflammation.

The pelvic organs showed evidence of recent inflammation; but neither these nor the intestines were carefully examined, since the evidence of the cause of all the symptoms had been clearly made out.

Remarks.—Here was a case of pelvic peritonitis extending into general peritonitis, and finally suppurative peritonitis of right side of abdomen.

On my first visit the symptoms were distinctly pathognomonic of peritonitis and pelvic cellulitis and slight pneumonia. The latter trouble improved; the symptoms of the second—pelvic peritonitis or cellulitis—viz., great tenderness in this region and the flexion of the thighs on the body, did not improve; and the evidence of general peritonitis of a chronic character remained.

The *tense* condition of the abdominal walls which I noticed at each visit, I believed to be due to the inflammation which had not fully subsided. Later, when a deposit of pus was believed to be present somewhere in the abdominal cavity, there being no pointing and no tumefaction, the searching for it with an aspirating-needle seemed no small undertaking, with so feeble a patient.

The lesson which I learned, and which in this somewhat detailed recital—and since so little is found in our text books and medical journals—I wish to teach, is this: when a patient has a peritonitis which is followed by a tedious and apparently unnecessarily lengthy convalescence, with an abdomen so sensitive to touch as to preclude a thorough examination, I should advise the administration of ether to relax the muscles as well as to produce less sensibility, and an examination by percussion and the hypodermic needle. Should pus be present, it should be drawn off with the needle or by free incision, as may seem most judicious at the time.

Reports of Hospitals.

THE SURGICAL CLINIC AT JEFFERSON MEDICAL COLLEGE HOSPITAL,

HELD BY SAMUEL D. GROSS, M.D., LL.D., D.C.L.,
OXON.,

PROFESSOR OF SURGERY.

(Reported for THE MEDICAL RECORD.)

- I. MYELOID SARCOMA OF THE HEAD OF THE HUMERUS.
- II. ERYSIPELAS INVOLVING THE SKIN AND THE SUBCUTANEOUS CONNECTIVE TISSUE.
- III. PARAPHIMOSIS AND ITS TREATMENT.
- IV. NECROSIS OF THE NASAL SEPTUM INVOLVING THE TUBINATED, AND THE PALATINE PROCESS OF THE SUPERIOR MAXILLARY, BONE.
- V. ABSCESS IN THE LEG, FOLLOWED BY THE FORMATION OF A SINUS.

This woman has been brought to the clinic by a medical friend from New Jersey, who wishes me to examine the case and advise with her parents regarding the propriety of an operation. You see at once that there is a large tumor situated on the superior extremity of the left humerus, and implicating a portion of the bone in the disease. The crepitation which I elicit by movement proves the existence of a fracture of the humerus at the lower part of the tumor. There is considerable swelling, but no discoloration of the integument. The pain is but trifling. The history shows that the patient fell on the ice last January, striking her left shoulder. The physician who was called in diagnosed the case to be one of fracture of the upper third of the humerus; but merely ordered the parts to be bathed with lead-water and laudanum.

There is considerable heat over the seat of the tumor. The patient states that her general health has been very good. She usually sleeps well at night, but occasionally she is wakeful, rendered so by pain in the growth. Her age is twenty-three years.

I need scarcely tell you that the growth is a sarcoma, commencing in the medullary structure of the head of the humerus, and terminating probably in the bone at the point of the fracture. There is, of course,

nothing to be done but to remove the limb at the shoulder-joint. Excision would be of no use. It is for the patient to determine whether or not the amputation shall be performed.

ERYSIPELAS INVOLVING THE SKIN AND THE SUBCUTANEOUS CONNECTIVE TISSUE.

This patient has been suffering for some time from a chronic trouble in his left knee-joint, for which I treated him some two weeks ago by an application of the actual cautery. You notice these large eschars on each side of the patella. The effects of the cauterization upon the joint trouble were most palpable and immediate; but, unfortunately, just when we thought he was on the fair road to recovery, an erysipelatous inflammation set in, attacking the left leg and the upper part of the left thigh, together with the right groin.

The inflammatory action is, as you see, entirely superficial, involving only the skin and superficial connective tissue. It is a very curious fact, but one which is very often noticed, that the erysipelas, instead of making its appearance near the seat of the disease or injury, occurs, perhaps, at a remote part of the body as on the trunk, abdomen, or superior extremities, when the injury is situated upon one of the legs.

A man cannot have erysipelas if his constitution is in good condition; cannot have it unless he has been exposed to some malarial influence, or has suffered from a poisoned condition of the system, or from a disordered digestion.

I regard erysipelas, of course, as a local manifestation of a constitutional vice. Such being the case, we must make use of constitutional as well as of local remedies. I have, in the present case, been employing quinia and the tincture of the chloride of iron. Locally I have ordered the resident surgeon to apply a solution of acetate of lead, which is better than either simple warm or cold water, or water medicated with any other substance. The solution which I always employ has a strength of a half-ounce of acetate of lead to the quart of water. After dipping a cloth in the solution and applying it to the parts, the dressing should be covered with a piece of waxed paper or of oiled silk.

After treating the local inflammation, it is necessary to keep an eye on the secretions; and when the saliva is scanty, the tongue coated, and the digestion more or less impaired, I order a few grains of calomel, to be followed in the course of six or eight hours by a small dose of castor oil. I prefer the oil to the Epsom and Rochelle salts. These latter drain off the serum of the blood, and so, of necessity, weaken the patient. The oil has no such effect if given in a moderate dose.

Erysipelas is a very peculiar affection. It follows a great number of diseases and operations—amputation, lithotomy, the lying-in state, etc. I have seen one case in which a leech-bite was followed by the fatal erysipelas. Indeed, the story is told of an eminent citizen of the West who lost his life from an attack of erysipelas following a *leech-bite*. In a recent case under my own care a most severe attack of erysipelas followed the operation for the removal of a small tumor from the face, and our patients are always in great danger from these attacks, unless the greatest care is exercised over the case and the proper treatment instituted at an early date.

There are several varieties of erysipelas: 1st, that involving the skin and subcutaneous connective tissue alone, of which the present case is a good illustration; 2d, the so-called *phlegmonous* variety, in which

the skin and subcutaneous tissues, muscles, and deep-seated structures—down to the very bone itself—are involved. In this variety the swelling is often enormous. Suppuration takes place, and there is a universal infiltration of the tissues with pus, which is diffused extensively in all directions—almost dissecting out the parts, as it were, with a knife—and not at all circumscribed; 3d, the *oedematous* variety, which is most liable to appear upon the face and on the male and female genital organs. It is accompanied by an effusion of serum, together with a small quantity of plasma. The oedematous form of erysipelas is generally a very mild one, occurring mostly in old persons and in those whose systems are worn out from disease or exposure, or both.

Erysipelas is a result of blood-poisoning, and is therefore frequently a very grave disease, liable to terminate fatally, unless very carefully managed.

As regards treatment, as I have already told you, the best local application is a strong solution of the acetate of lead. Tincture of iodine diluted with an equal quantity of alcohol is also a valuable remedy; while in the milder forms of the disease zinc ointment occasionally answered good purpose. Sometimes simple emollient remedies, such as gum arabic, or flaxseed, either alone or with acetate of lead and laudanum, are productive of great benefit.

In all cases you must pay special attention to the constitution. When the appetite is poor, the liver torpid, and the alvine evacuations irregular; when the whole body aches, or profound lassitude supervenes, mercury should be employed, taking care that it does not act too briskly. In addition to the mercury you should, for their tonic effect, give quinia and the tincture of the chloride of iron. If there is much circulatory excitement the patient should be kept under the influence of two-drop doses of the tincture of the root of aconite, given three or four times in the course of the twenty-four hours.

A change of air is always desirable. Pure oxygen is a great desideratum in this condition. The ventilation must be good and the diet nourishing.

If it is the phlegmonous variety with which you have to deal, the local treatment should be conjoined with free incisions, thus providing an outlet to the effused serum and plasma, for, otherwise, the unhealthy action may run into suppuration, and pus is always a destructive agent, and may do great harm if allowed to remain pent up; harm which it may take weeks, and even months, to remedy.

When you meet with a case of erysipelas in the wards of a hospital, the patient should at once be put in a room by himself. If the weather be hot, he had better be quartered in a tent outside of the building, where there is an abundance of fresh air and sunshine.

PARAPHIMOSIS AND ITS TREATMENT.

This young man is about eighteen years of age. On the night of Thursday, October 16th, he had impure connection. On the following Sunday, October 19th, he was first conscious of soreness and throbbing of the penis. The organ became greatly swollen and much inflamed. When seen at the outdoor clinic there was so much phimosis that the prepuce could not at first be retracted. When retraction was finally effected, on the following day, five sores were brought to light on the glans penis. These sores were at once cauterized, and the patient was told to bathe the parts frequently throughout the day with warm salt water. When the prepuce had been retracted for some hours the

glans penis began to swell greatly, and well-marked paraphimosis supervened. The only treatment of this condition thus far has been by bathing the parts with warm salt water and by position.

You will notice that, according to the history of the case, the phimosis disappeared when the foreskin could be drawn back, and that there was a considerable amount of infiltration of serum and lymph accompanying the phimosis. No sooner was the phimosis relieved than a violent paraphimosis was set up, marked by much oedema and great enlargement of the head of the penis.

The five sores were evidently five soft chancres. In soft chancres the ulcerative action is superficial, and extends rapidly, which is by no means the case with the hard chancre, where there is but slight discharge. In only about one case out of every four is the soft chancre likely to be followed by a bubo, whereas the hard chancre is always, or nearly always, so followed. These five soft chancres are very nearly healed to-day.

The cure of paraphimosis depends, of course, upon the reduction of the prepuce to its natural condition. In cases of recent standing, such as the present one, this is a matter of but very slight difficulty. When the infiltration, however, is very great, the reduction is very difficult. What we have to do in these cases, where infiltration has progressed to a great extent, is to place the patient under the influence of an anæsthetic, so as to render him insensible, and thus prevent him from offering any resistance. The surgeon should then grasp the organ behind the retracted prepuce, gradually force the blood out of the head of the penis, and press the head of the penis back while he draws the prepuce forward. This compound movement generally suffices to effect the reduction of the parts.

It has occurred to me that we might diminish the size of the head of the penis in these cases by applying a narrow band of gum elastic around the part, but this is not always practicable or possible.

When the surgeon is unable to effect reduction by the compound movement referred to above, he must proceed at once to make an incision through the stricture formed by the prepuce, with a bistoury. In all cases where the infiltration is great, incisions must be made into the parts inundated, in order to allow the serum to drain off. The penis, when paraphimosis exists, should never be allowed to hang down, but must be so placed as to point toward the umbilicus. If the swelling do not yield to the solution—acetate of lead—which we are using in the present case, we shall apply mercurial ointment as an absorbent, before attempting any operative measures.

NECROSIS OF THE NASAL SEPTUM INVOLVING THE TURBINATED, AND THE PALATINE PROCESS OF THE SUPERIOR MAXILLARY, BONE.

This woman is thirty-nine years of age. Eight years ago she began to suffer from nasal catarrh, which has persisted ever since. For the last two years the discharge has been very offensive, and has frequently contained fragments of diseased bone. Examination of the roof of the woman's mouth reveals extensive ulceration there. There is evidently necrosis of the nasal septum and turbinated bone, involving the palatine process of the superior maxillary bone. By means of a speculum, designed for the examination of the nose and anterior nares, I can plainly see the seat of necrosis, and upon introducing this polyp-forceps I come at once in contact with a piece of dead bone, which I shall im-

mediately proceed to remove. It is an exceedingly bloody and painful operation, but the woman bears it very bravely. I think that I have now succeeded in getting all the sequestra away. If the bleeding becomes unmanageable at any time, or if secondary hemorrhage should chance to ensue, the resident surgeon will have to plug the nares.

ABSCESS IN THE LEG, FOLLOWED BY THE FORMATION OF A LONG SINUS.

The abscess was not properly attended to in this case, and it has been followed by a sinus. I dwelt at considerable length at my last lecture on phlegmonous abscesses, and referred to the fact that sinuses often follow them.

This sinus has existed since the 26th of last July. There has been a large and constant discharge of pus from it. There are no healthy granulations, either within or around the opening of the sinus. The granulations which can be seen have not the elevated appearance indicative of robust, but on the contrary, present all the characteristics of unhealthy, action. There is a great deal of redness in the adjacent tissues. When I press upon the parts, they become blanched, but the blood returns to the surface the moment that the pressure is withdrawn.

The man is thin; his tongue is coated, and his digestion is poor. I find, upon inserting a probe, that the sinus extends up the limb toward the knee, a distance of nearly three inches and three-quarters.

How is the case to be treated? I have told you upon numerous occasions that the best plan is to lay a sinus freely open throughout its whole extent, and so allow it to heal from the bottom. Some authorities have suggested the injection of caustic or astringent solutions, and advised the subsequent employment of systematic compression; but none of these remedies are of much permanent account. We might insert a seton, but I never did approve of this nasty, filthy alternative.

It is always necessary to scrape the unhealthy granulations away throughout the whole extent of a sinus, and at the same time the undermined skin should be dissected from the aponeurosis for a considerable distance, so that healthy granulations may spring up. The sides of the sinus should then be brought together and a roller applied; a few adhesive strips are also needed so as to effect slight approximation.

You see here exemplified the bad effects of an accumulation of pus, all of which might have been avoided by a free and early incision, as is my invariable rule in all such cases.

Progress of Medical Science.

DIABETES DEPENDENT UPON LESION OF THE PANCREAS.—In 1879, M. Lanceroux described a form of diabetes which had its origin in lesions of the pancreas. Since then, his pupil, M. Lapiere, has made a special study of this question, and given a valuable addition to its literature. The disease is marked by its sudden onset, and, from its inception, it is manifested by grave intestinal troubles, rapidly followed by polydipsia, polyphagia, polyuria, and glycosuria. In a few months the patient becomes greatly emaciated, he loses successively his physical, intellectual, and virile powers, sinks gradually into a state of exhaustion, and finally presents the symptoms of pul-

monary phthisis. The total duration of the disease varies from six months to three years, the average being about twenty months. In addition to the general treatment indicated in all forms of diabetes, we have in these cases to attack the primary lesion. Unfortunately our efforts in this direction are of but little avail, being confined to endeavors to supply the function of the pancreatic juice by increasing the action of the auxiliary organs and by the artificial digestion of the food.—*Gazette des Hôpitaux*, Oct. 18, 1879.

SPONTANEOUS DISAPPEARANCE OF LYMPHADENOMATOUS TUMORS.—At a meeting of the London Pathological Society, Dr. Coats, of Glasgow, related the case of a man who, when first under the surgeon's care, had had a number of small tumors in the abdominal walls. These, for the most part, disappeared, but others in time took their place. In about ten months as many as thirty-four were present; the man then became much worse, and finally died from vomiting and exhaustion. Post-mortem examination showed numerous tumors not only in the subcutaneous connective tissue, but also in the connective tissue of the abdomen, in the mesentery, and about the kidney. These tumors were found to be of lymphoid character.

The history of this case, which appeared to be unique, brought out the fact that similar ones had been observed, and that the occurrence of unstable lymphadenomatous growths was not so very rare. One has been reported by Dr. Duhring in this country under the head of "Inflammatory Neoplasm." Hebra has observed a case, and Sir James Paget and other members of the Society reported several. Such cases have sometimes been mistaken for cancer.

In their treatment, remarkably good results have been obtained from liquor arsenicalis and iodide of potassium.—*Med. Times and Gazette*, May 17, 1879.

HYSTERIA IN BOYS.—Dr. William Roberts contributes the history of several cases of hysteria in boys to the November number of *The Practitioner*. In prefacing these histories he mentions similar cases reported by other observers, but under different names; there being an unwillingness to apply the term hysteria to males.

The first case was that of a boy of thirteen. After some trifling ailment, he began to be hypochondriacal and low spirited. Eight months later he was attacked with a cough which soon changed into a true hysterical bark, and then into a kind of bleating noise. He kept this up nearly all day for several months; he then went through the exercise only at morning and night. The symptoms continued for about fifteen months, when the boy became perfectly well. The hysterical nature of this case was well marked. The mother had been hysterical when a girl, and the brother and sister were also affected for a short time. The disease in the latter persons took the same form of bleating, and was evidently brought on by unconscious mimicry.

The second case was that of a boy of eight or nine years. The hysterical symptoms in his case came on, as is not unusual, during convalescence from acute disease. The boy became suddenly subject to attacks of loud, passionate, tearless crying, with incoherent ravings of a most alarming and distressing character. These continued for a week; they then ceased for a week, to be resumed again, though with less severity. During the intervals between the paroxysms the boy seemed perfectly well. A removal from home surroundings and sympathy, with the daily use of the galvanic current, resulted in cure.

Case number three was an exquisite example of hysterical contracture. A healthy boy of eleven, while walking to church, began to limp. By the time he reached home his left foot was contracted inward in the position of extreme talipes varus. Under chloroform the spasm relaxed, but no force or mechanical appliance could keep it in proper position. There having been no injury, fever, or pain, the case was diagnosed as hysteria; the boy was encouraged to get up and try to use his foot. This he did, and in twenty-four hours was quite well.

The fourth case was one somewhat simulating epilepsy. A healthy, well-grown boy became gradually subject to short convulsive attacks, affecting the whole body. They occurred early at night or toward morning; afterward they took place in the daytime also. He remembered nothing of the attacks himself. There was no frothing at the mouth, or biting of the tongue. The boy suffered in this way for nine months, and then gradually improved, until he became quite well.

These cases prove the existence of hysteria, of undoubted character, in boys.

THE ANATOMICAL CHANGES IN THE LYMPH-GLANDS IN TUBERCULOSIS, IN AMYLOID DEGENERATION, AND IN TUMORS.—The following are the chief points of a paper by Prof. Cornil on the pathological changes of the lymphatic glands—a subject which he regards as of especial interest, because these changes are almost exclusively secondary to the so-called diatheses or affections of other organs, and because, from their character, conclusions can be deduced concerning the nature of the primary affection:

1. In *acute adenitis suppurativa*, the sinus, the lymph channels, and the cavernous tissue of the gland are filled with pus, which is also found in the connective tissue surrounding the capsule, and in the lymphatics that are connected with the gland.

2. *Syphilitic adenitis* is characterized in the primary and secondary periods by swelling and proliferation of the nuclei of the sinus-cells, together with moderate thickening or sclerosis of the connective-tissue framework. The latter is very marked only in the so-called strumous buboes of syphilis. In the tertiary period we meet with various forms of change: the glands may be indurated, cirrhotic, sclerosed, or cheesy. A rarer form of lesion is the so-called medullary adenitis; in this the entire cavernous or follicular substance is the seat of a chronic, what may be called catarrhal inflammation, the connective-tissue framework of the gland being unaffected. Such a gland is swollen and soft, and on section looks like the brain substance; it contains a whitish, milky juice.

3. In *scrofula* the glandular lesion is the sequel of a chronic inflammation of the skin or mucous membrane in a predisposed person. The lesion consists essentially in a chronic inflammation of the connective tissue, in a fibrous thickening of the original septa, which leads secondarily to the formation of isolated foci in the reticulated substance. The caseous degeneration of these nodules is due to the impeded circulation consequent on the primary sclerosis of the connective tissue.

4. *Tuberculous* lymph-glands resemble the scrofulous only in one particular—viz., in the tendency to undergo caseous degeneration; in all other respects the two processes are entirely different. In scrofulosis the glands become very large; in tuberculosis they usually remain small. In the latter the initial process is located in the lymph-channels and the perifollicular sinus; it is a distinct inflammation,

characterized by the accumulation of numerous large cells in those parts. The scrofulous affection begins as an interstitial adenitis, as a new growth of the connective-tissue framework. In the fully developed state we find in the *tubercular* affection the characteristic tubercles—i. e., small, isolated collections of minute, closely-packed round cells, which often enclose giant-cells and readily undergo caseous degeneration, while in the *scrofulous* affection the characteristic change consists in the isolation by the newly formed connective tissue of small islands of reticulated tissue filled with large lymph-cells. When one of these islands becomes caseous, the degeneration attacks the whole of it at once and progresses slowly, while the caseification of a tubercular nodule begins in the centre and extends rapidly.

5. In *amyloid degeneration* the enlargement depends on a chronic inflammation, which is both interstitial and catarrhal. Only the vessels of the cortical layer and the cell-masses of the cavernous tissue in contact with them, become waxy.

6. With regard to *tumors* of the lymphatic glands, the author simply lays down the following axiom: they reproduce faithfully the anatomical form of the primary tumor, and are produced by direct metastasis of its elements.—*Allg. Med. Cent. Zeit.*, September 20, 1879.

“BLOODLESS METHOD” OF PERFORMING TRACHEOTOMY.—Dr. Reismann, of Haspe, Westphalia, describes an ingenious method of securing local bloodlessness in the operation of tracheotomy, which he has tried with success in one case. The incision made was only 2 cm. ($\frac{1}{2}$ in.) in length, and carried down to the superficial fascia. The sides of the wound were then made to gape by lateral pressure with the fingers, and nine sutures were introduced with a delicate, curved needle, through the skin and the tissues covering the trachea, the point of the needle being carried as closely as possible to the trachea. The sutures were secured by single slip-knots, which were only drawn tightly enough to control temporarily the flow of blood, and the ends were given to an assistant, who, by slight traction on them, made the wound gape a little more. The operator then rapidly opened the windpipe and introduced the canula. As soon as this was fixed in place, the ligatures were loosened by simple traction on one end of the thread, and were withdrawn from the tissues. After the removal of the ligatures, there was scarcely any bleeding. If any had occurred, Dr. Reismann thinks it could have been easily controlled by pressure on the plate of the canula, and by the introduction under it of pledgets of tannin-cotton.—*Berliner klin. Wochen.*, Sept. 8, 1879.

DUPLICATING PRESCRIPTIONS.—A recent medical act in Wisconsin reads as follows: “If any physician practising medicine in this State shall write or cause to be printed on any prescription the words ‘No duplicate,’ any vender of medicines who shall duplicate such a prescription without the physician’s consent shall be subject to a fine of \$10 for each offence.”

The *Louisville Medical News* comments as follows: “We wish this law prevailed in Louisville. Here one prescription, gotten on credit, and often never paid for, is used by an individual or a family indefinitely, and besides, is often loaned to friends and relatives. It is pleasant to know, however, that the modest and moderate-charging druggist gets his little one hundred per cent. every time the \mathcal{R} . is filled.”

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 20, 1879.

THE MEDICAL HISTORY OF THE WAR.

THE second part of the "Medical History of the War" is before us, and is a trifling matter of eight hundred and sixty-nine quarto pages. The first part of this medical history, issued in 1875, was made up mostly of statistical tables showing the diseases and deaths from which the army had suffered. Statistics in quarto form are not an attractive kind of literature, and consequently Part One has never been a popular work. The present volume covers a very different ground, treating of the alvine fluxes. It is in every way a noteworthy book, and one with whose value the medical profession should be familiar. Dr. Woodward has made a conscientious and thorough use of the magnificent materials at his command, and there is no exaggeration in saying that he has produced the most complete and exhaustive work on a medical subject that has ever been published. The medical profession, and especially American physicians, are to be congratulated that a volume so creditable to medical science has appeared.

A partial outline of the contents will give some justification for these statements.

The alvine fluxes are treated of at great length, on account of their prominence on the sick and mortality lists of the army. Of the 171,704 deaths from disease, 57,265, or about one-third, were caused by diarrhoea or dysentery. From five to ten per cent. of the troops were always on the sick-list from the same diseases. As the war advanced the mortality increased, until it had reached the number above given; and this does not, probably, represent the whole. As the deaths from acute diarrhoea were in the proportion of 1 to 395 cases, those from acute dysentery 1 to 57 cases, and those from chronic dysentery and diarrhoea 1 to about 4 cases, the immense number of persons subject to these fluxes can be imagined.

Dr. Woodward's treatment of the subject before him is in some respects original, as it is practical and exhaustive. He divides the fluxes into: 1. Acute diarrhoea; 2. Acute dysentery; 3. Chronic diarrhoea and dysentery; and, 4. Tuberculous diarrhoea. Under each head are given a history, with bibliographical notes; the pathology and morbid anatomy, most elaborately illustrated with woodcuts, photographs, chromo-lithographs, and steel engravings; then, in addition, are the usual topics of etiology, symptoms, course, and treatment.

The divisions which include the morbid anatomy and pathology will attract the most attention. They are mines of pathological lore as far as the particular subjects investigated are concerned, and much information upon allied questions in general pathology is also given. Inflammation and tuberculosis are instances of this branching out of the work. The photographs are excellently done, the micro-photographs being of sections magnified but sixty-three diameters. In thus using only the lower powers, the comparatively small value of high-power photographs is very properly recognized. Not much that is positively new could be expected from investigations of such easily studied lesions as those of the fluxes; but the presentation of these lesions has never before been so fully made. The most important practical contributions, however, are in the assignment of clinical symptoms to their proper anatomical lesions. The too prevalent misapprehension, especially among American practitioners, that diarrhoea is located chiefly in the small intestine, is referred to. In the cases examined, the parts most extensively affected in acute diarrhoea were the caecum and sigmoid flexure, and, next to these, the ileum.

Chronic diarrhoea and chronic dysentery are treated together, for it was found impossible to make any satisfactory clinical distinctions between them.

Under the head of tubercular diarrhoea a full account of the tubercular process is given. Dr. Woodward expresses two tolerably positive opinions with regard to this much-discussed morbid disturbance: first, that the so-called giant-cells, said to exist in the ultimate tubercle, are figures resulting from the action of reagents upon sections of lymphatic vessels stuffed with coagulated fibrin; and, second, that the development of the ultimate tubercle is determined by the formation of a small fibrin clot obstructing a small lymphatic vessel.

Acute diarrhoea and acute dysentery were found to shade into each other so gradually, that distinction on any grounds was often difficult. Clinically, however, the symptom of tenesmus is, somewhat arbitrarily, assumed to be pathognomonic of acute dysentery. Anatomically, in dysentery, the ulcerations, the diphtheritic exudation, and the lower situation of the lesion mark the character of the disease in all but the mild cases. Very often mild forms of acute catarrh

ral dysentery are not distinguishable, anatomically from acute diarrhoea.

Passing over the subject of etiology with the statement that the contagiousness of dysentery is not allowed to have been proved, we come to the discussion of the treatment. This covers ninety pages. The value of every drug that has ever attained reputation in the treatment of diarrhoea or dysentery, from the time of Hippocrates down, is exhaustively examined. Some of the writer's conclusions are, that ipecac has but problematical value in acute dysentery; that in the same disease, calomel, whether in large or small doses, is not a remedy to be advised. Oil of turpentine and camphor receive the slightest possible commendation. Purgatives are recommended, but not castor-oil. Sulphate of magnesia, the neutral salts, and rhubarb, are to be preferred. A small work on *materia medica* might be compiled out of this discussion upon the therapeutics of dysentery and diarrhoea. We cannot adequately comment upon it here.

We have given quite unreserved praise to this book, and such it deserves. Our Government, which has begun to gain some reputation abroad for the scientific work it has set on foot, will get in this, as in its companion volumes, credit for having done what no other nation has attempted or can attempt. This credit will be reflected upon our own profession at home, which is doing more every year to prove that Americans are capable of legitimate scientific work.

There is but one regret to express in this connection. The present work is too bulky and costly for very wide distribution. Besides this, the practical parts are so buried in voluminous details, that the whole becomes valuable almost solely for reference. It would be most desirable if a condensed work could be made in which the statistical tables, bibliography, some of the history, and all superfluous discussion should be left out. Such condensation, properly made, would have a place among the classics of medical literature. In its present form it earns the title of "The Book of Magnificent Proportions;" but one cannot lift it to the niche of those immortals on whom dust will not gather.

CHICAGO AND THE LIMITS OF SANITARY INTERFERENCE.

The history of sanitary measures in Chicago is one which, on the whole, does the city great credit. Situated as it is, largely upon swampy ground, whose average elevation above the lake is only twelve feet, and exposed to strong winds and sudden changes of temperature, it would be natural to expect a high percentage of mortality. Through its energetic attention to sewerage, however, and through the establishment of its magnificent water-works and extensive parks, it has reduced the death-rate to eighteen per thousand, which is less than the average in large cities.

Encouraged by such results, doubtless, the Board has of late displayed an increased energy of action, which has at length raised up much opposition among the more conservative. Some time ago, red placards were ordered to be hung on the door of every house in which there was a case of scarlet fever; the Health Commissioner has been inspecting the meat markets, and has attempted to confiscate bad meat; the milk, too, has been inspected, and efforts made to limit the increase of its watery constituents; the foul odors from rendering establishments have been abolished; the public libraries have been inspected, and the possibility of contagion through circulation of the books examined into and provided for; the tenement-houses have been visited, and police authority exercised to secure the bettering of their condition; registration of births and deaths, as well as notification of the appearance of contagious diseases, are, of course, demanded of the physicians.

The discussion that has been excited by the very active manner in which all these measures have been carried out, raises some interesting questions. There is, for instance, a decided lack of definite knowledge as to where municipal sanitation should end and private effort begin. If public authority goes too far, it will excite alarm and distrust; furthermore, private organizations, as a rule, do vastly better work than public ones, and in sanitary matters it is instruction that is needed quite as much as authority. The principle, that sickness does not make a man a criminal, and that the government has no right to injure the private citizen even for the public good, without some compensation, should be in general the guide in drawing the line where sanitary interference should end. We are disposed, therefore, to take a conservative view of the question in hand. There is a tendency just now to an excessive display of sanitary efforts; and some of these, without advancing the public good, curtail the liberty of the individual, and impose especially upon the doctor. The confiscation of damaged meat, the placarding of houses in which scarlet fever exists, and the compelling physicians to report births, deaths, and infectious diseases, are among the measures whose enforcement has excited either open opposition or secret evasion.

We shall not attempt to discuss the particular merits of the first two points, as they have as yet no great significance to the most of the profession. Upon the subject of compulsory registration, however, some recent discussion and action have occurred that deserve attention.

For fifteen years the medical profession in Great Britain, appreciating the importance of the early notification of cases of infectious disease, has urged the adoption of a compulsory registration. Their efforts have been largely successful, but the compulsion has, contrary to the advice of the British Medical Association, been laid upon the doctors instead of upon

the householder in charge of the disease. At the last meeting of this Association, the committee deprecated in strong terms this arrangement of the matter, and presented a number of reasons against it. These are, briefly, that it placed the physician in the position of an informer upon the affairs of his patient; that it is unjust to add to the danger incurred by medical men in attending upon infectious diseases, the possibility of indictments and fines for not making a report which an arbitrary enactment demands of them; that such an enactment leads people to evade it by not calling in medical help; that any injury to business caused by the physician's giving notice of the disease is liable to be ascribed largely to such medical attendant; and, in case of disputed diagnosis, much trouble may result.

There is justice in these arguments, and they come from high authority. It is certainly an imposition upon the doctor to oblige him to be responsible for the notification of contagious diseases; there is no question of the injustice, morally speaking, at least, of subjecting him to heavy fines in case of failure in the imposed duty. Practically, however, the imposition does not appear to be so oppressive, and it is certainly the easiest and most convenient way of getting at the facts; the doctor would always have to help the householder make out his report, and would often have to be both his stationer and amanuensis.

While denying the justice and admitting the occasional inconveniences, therefore, of placing this obligation upon physicians, it seems unnecessary to make any special protests until the members of the profession express themselves more strongly, either against the law or in favor of compensation for being placed under it. Individual complaints should come first.

The exact limits of proper and just sanitary interference cannot yet be defined. We will have to learn them largely by practical experience, and they will always have to be of sufficient elasticity to meet the emergencies of great epidemics. Meanwhile the profession should see that the dash and *clém* of the modern sanitarian result in no unnecessary or uncalled for encroachments on the personal liberty and rights either of themselves or their patients.

MEDICAL RECEPTIONS.

THE old saw, that all work and no play helps to make the subject of that condition a dull boy, has a striking application to members of our profession. At best, our calling is an exacting and tiresome one, and its followers need something to offset a more or less continuous mental strain. We are glad to see that the old notion that the physician must be different from other men, is fast passing away. On the contrary, some of our best workers are those who seem to enjoy life the most. They are to be seen at the opera, the theatre, the concert hall, and at the fashionable receptions, with a regularity that would surprise the

man who says he never has time to do anything but strictly professional business. The secret of the whole matter is, that some amusement gives in the end a better capacity for real work, when the latter is necessary. It is a promising sign that such amusements are beginning to be common among medical men. Medical receptions are becoming quite frequent, and their enjoyable character is likely to make them still more popular. Aside from showing honor to distinguished strangers, we know of no means better calculated to edify the man medical as a social being, and to give him a closer sympathy with his medical brother, than the receptions to which we allude. On such occasions the individuals meet on the common ground of enjoyable sociability, and lose sight of mere differences of opinion in a common desire to be happy themselves, and agreeable to their companions. Already the receptions which have been recently held are beginning to bear good fruit, transforming apparent strangers into congenial associates, and in creating a better understanding with all as to the true relation which professional gentlemen should bear to each other. We have a slight suspicion that the expression, "the more the merrier," will not be considered original with us, but it is nevertheless applicable to the occasion.

SUITS OF MALPRACTICE.

THE resolutions of the Medical and Surgical Society of Baltimore, bearing upon the frequency of suits for malpractice and their prevention, are timely and in keeping with the general sentiment of the profession. When it is known that almost always the foundation for such suits is laid by an ill-advised remark of a brother practitioner, if not by open hostility on his part, the manner in which the profession can protect itself becomes quite apparent. Not only should such remarks be discouraged, but members making them should be disciplined by the societies. It is bad enough to be compelled to testify as an impartial expert, but when one becomes a willing witness against his brother, he fathoms the lowest depths of professional meanness. The way to prevent such possibilities is, as the Baltimore Society suggests, to be on the safe side by actively discouraging all such suits. No medical man can afford to raise himself at the expense of belittling his profession by attempting to prove that his rival is an ignominium.

IMPROVEMENT OF THE BLIND.—A Society for the Improvement of the Physique of the Blind has been founded in London. Its object is to improve the physique of the adult blind, to assist the physical education of blind children, and to prevent blindness in children, as far as possible, by teaching the hygiene of the eyes. It expects to train teachers for these purposes, to introduce physical exercise into blind-asylums, and to collect information regarding the causes of blindness.—*Brit. Med. Journ.*

Reviews and Notices of Books.

THE PHYSICIAN'S HANDBOOK FOR 1880. By WM. ELMER, M.D., and A. D. ELMER, M.D. New York: W. A. Townsend.

THIS handbook, which is now in the twenty-third year of its publication, is certainly a *multum in parvo*. It contains a list of the diseases which are usually met with in practice, with a brief epitome of the symptoms and treatment of each, short articles on emergencies and their treatment, on poisons, their symptoms and treatment, and on the diagnostic examination of the urine; lists of incompatibles and of antagonistic remedies; tables of weights and measures; a condensed list of remedial agents, with their preparations and doses; and an article on the art of prescribing. After all this, we have an alphabetical ledger, a daily visiting-list for the year, obstetrical and diagnostic records, and a space to enter cash received. As might be expected, the attempt to include so many things in one volume has made it rather bulky for pocket use. The book is published in the usual style of a visiting-list; it contains 314 pages.

TRANSACTIONS OF THE NEW YORK PATHOLOGICAL SOCIETY. Vol. III., pp. 335. Wood & Co. 1879.

THE contents of this third volume consist of reports of three hundred and thirty-six cases and specimens presented during the year 1875, with a supplement of numerous similar cases selected from the archives from the year 1844. There are three classes of subjects: diseases of the organs of digestion, continued from Vol. II.; diseases of the genito-urinary tract; and observations in one hundred cases of cancer. In each department the collection indicates careful pathological research. The diseases of the liver, of which there are seventy-one cases; of the gall-bladder, ducts, etc., thirty cases; and of the spleen, thirty-two cases,—are grouped with reference to parenchymatous and interstitial changes (due chiefly to chronic disease), degenerations, growths, malformations, and eccentricities. Carcinosis, waxy and fatty degeneration of the liver, hypertrophy and infarction of the spleen, form a large array of these diseases. John C. Peters gives a concise history of yellow fever in New York; Francis Delafield reports a case of red atrophy of the liver—a rare form of hob-nailed disease, due to contraction of the hepatic cells; E. G. Janeway presents a furrowed liver, the furrow being due to obstruction of the portal vein; Thos. M. Markoe contributes an unique specimen of acute miliary tubercular disease of the liver. There are no less than six cases of rupture of the spleen, all traumatic; a note suggests that this accident has been seen in typhoid, remittent, and relapsing fevers, and in cholera.

Considerable space is devoted to pyo-nephrosis and nephrotomy, cases of which, with the operation, are detailed by Alfred L. Loomis and F. D. Lente. Lente's operation of nephrotomy is the first instance on record in the literature of the last two hundred years, where the term is limited to "cutting down upon an ureter or kidney *entirely free from perinephritic disease or adhesion*, with no guide except the anatomical relations of the parts." This limitation corresponds with the signification of Rayer, Civiale, and Desault. Mr. Bryant's and Mr. Anandale's operations were for pyo-nephritic abscess.

There is a large category of renal cysts, and a few, too briefly noted, cases of tuberculosis of the kidney. This is a rare form of disease, easily mistaken for pyo-nephrosis, and sometimes called strumous pyelitis. Forty-four cases of affections of the bladder are noted, of which ten are ruptures; eight of the ten have a traumatic origin. So rare is a rent in the bladder in connection with a stricture of the urethra, that Sir Henry Thompson never saw it; Sir Everard Home noticed two cases, and Pitha refers to one case. Gurdon Buck's new method of puncture of the bladder is detailed—viz.: by incising, as in the bilateral operation for lithotomy, and following up the cut with the thumb in the wound and finger in the rectum, until the position of a previously introduced full-sized sound is reached. There are twenty-two cases of diseases of the Fallopian tubes and eleven of superfetation.

The observations in regard to cancer were made for the purpose of considering: (1) the accuracy of the microscope as a means of diagnosis; (2) longevity, as increased by the knife; and (3) the best treatment. The one hundred unselected cases are from St. Luke's, Presbyterian, and New York Hospitals, the Pathological Society, and the College of Physicians and Surgeons. The cases are extensively tabulated, where it will be seen that ninety-five per cent. were examined by competent microscopists. Drs. Satterthwaite and Porter have done their work so carefully, that fifty-seven cases have been completed from the inception of the disease to death. The drawings are by Mayer, Satterthwaite, and Amidon.

The third volume will rank with the previous ones as a text-book of pathology. The editor is to be congratulated on the character of their favorable reception by such authorities as the *Edinburgh Medical and Surgical Journal*, whose notices appear in the preface; while the present reviewer attests to the announced opinions of Billroth and the Librarian of the Royal College of Surgeons, London, made in private conversation.

A BIOGRAPHICAL DICTIONARY OF CONTEMPORARY AMERICAN PHYSICIANS AND SURGEONS. Edited by WILLIAM B. ATKINSON, M.D. Second Edition; Enlarged and Revised. Philadelphia: D. G. Brinton. 1880.

THE present is hardly an improvement on the first edition of this work. The paper, if possible, is poorer than before, the type old and more worn, and the portraits are omitted. This latter circumstance is no particular calamity, except so far as it detracts from the general appearance of the volume and denies the reader the opportunity of amusing himself with the vanities of others.

There are a number of new biographies, sixteen pages of which form an appendix to this condition, and two pages of corrections. Each of these additions is provided with a separate index. Why the subjects should not have been incorporated in the body of the work does not appear, unless perhaps that, with the exceptions noted, the work is printed from the stereotype plates of the former edition. Dr. Atkinson is still the editor—the publisher being D. G. Brinton, of Philadelphia.

CHICAGO MEDICAL GAZETTE.—The first number of this new bi-weekly journal is at hand, and is a very creditable issue. Dr. E. C. Dudley is the editor.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Nov. 12, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

SARCOMA OF SUPERIOR MAXILLA.

Dr. Mason exhibited a section of the cranial and facial bones, showing the termination of a sarcoma of the superior maxillary bone. The patient from whom the specimen was removed was a widow, aged thirty-four years. Dr. Mason saw her, for the first time, during February of 1878, when she was sent to Roosevelt Hospital. Her history then was, that two years previously she had an abscess of the left upper jaw, supposed to be due to a defective tooth. After the abscess discharged itself, a small, soft, smooth growth made its appearance on the opening, and continued to increase in size.

At the time of her admission to the hospital, the whole superior maxilla seemed to be involved in the growth. She suffered from intense pain, the left eyeball protruded, and the sight was defective. Her general condition was much below par, so that the operation was deferred for a month, she having been under tonic treatment in the meantime.

The entire superior maxillary bone was removed in March, 1878. On examination, the growth was found to be a spindle-cell sarcoma. She speedily recovered from the operation, the pain was relieved, but the vision still remained defective. She left the institution, apparently perfectly well, in August of that year.

In March, 1879, she called on Dr. Mason, when the disease was found to have returned. A growth of considerable size was found projecting into the mouth, was very vascular, and had occasionally given rise to hemorrhage through the mouth and nose. She was again sent to the hospital. Dr. Weir then removed all the growth within reach. She recovered speedily from that operation, but soon the growth again appeared, increased rapidly in size, and was attended by profuse hemorrhages, necessitating the frequent application of Paquelin's cautery. She gradually failed, and died July 16, 1879.

A careful autopsy was made. The base of the nose was protruded, and the cavity of the left nostril was completely plugged by the growth, the latter making its way externally. The space formerly occupied by the superior maxilla was filled with sarcomatous tissue, also the posterior nares, a portion of the pharynx, the sphenoidal and ethmoidal cells, and lastly through the sphenoidal tissue into the middle fossa of the skull. In the latter locality the growth was the size of a pigeon's egg. The left optic nerve was found surrounded by the neoplasm.

In answer to a question from Dr. Seguin, Dr. Mason stated that there were no cerebral symptoms manifested, save those that were due to loss of blood.

CARCINOMA OF THE RECTUM—LUMBAR COLOTOMY.

Dr. Howe presented a specimen of carcinoma of the rectum, removed from the body of a female upon whom lumbo-colotomy had been performed.

Anne Porlome, *æt.* 58, a native of Bohemia, was admitted to St. Francis's Hospital, Feb. 19, 1879. She

could not speak English, and all the history attained—a meagre one—was given by her brother.

Eleven weeks previous to admission she began to feel pain on defecation, which gradually increased as the disease progressed. There was also great difficulty in emptying the bowels. Some blood came away with the feces. Fecal matter was stringing out reddish yellow in color. She was confined to her bed for several weeks previous to coming to the hospital, and had been one week without an evacuation of the bowels.

On examination, the patient exhibited well-marked cancerous cachexia. She suffered intensely. The abdomen was greatly distended and tympanitic. Pressure over it occasioned pain. The rectum seemed completely closed by irregular masses of new formations, which were soft on the surface and which bled freely. There was a small, but constant discharge of pus and blood from the rectum. The margin of the anus was red and indurated.

An attempt was made to move the bowels by passing a gum-elastic catheter beyond the mass which closed the rectum, and injecting warm water and sweet-oil. Castor-oil was also given internally, but all failed to give relief.

On the third day after admission I performed lumbar colotomy in the usual manner. When the gut was opened, there was considerable discharge of gas, with small portions of hardened feces.

Patient was ordered hypodermic of morphia, ten minims, and ten grains of quinine. Morning after the operation pulse was 146, temperature 102°. Had six passages through the artificial anus during the day. On the 3d, three days after the operation, patient was very comfortable, had little or no pain; temperature, 101°; pulse, 102. General improvement continued. One week after operation sutures were removed—upper portion of wound healed by first intention—lower portion was ununited and suppurating freely. Pulse, 100; temperature, 100.

On March 7th there was some prolapse of the gut, and diarrhœa, which was early checked. Wound healed. Patient continued free from pain; her appetite returned as she gained in strength, until she left the hospital in June. She afterward went to Ward's Island Hospital, where she remained until she succumbed to cancerous disease of the rectum, September last. Her life was prolonged seven weeks.

In answer to a question from Dr. Briddon, Dr. Howe stated that the prolapsus was three inches.

Dr. Bardon referred to a case in which the prolapsus was the length of the arm. In his own cases, four in number, there was no protrusion through the new anus. He did not believe that the kind of incision, whether straight or oblique, had anything to do with the result.

In connection with this subject of lumbo-colotomy Dr. Mason referred to a case in which sudden death after the operation was due to copious alvine evacuations. Two or three similar cases were on record as having occurred abroad, but his was the first of the kind in this country.

Dr. Howe presented a second specimen, consisting of a calculus removed from a female bladder by dilatation of the urethra.

LITHOTRITY IN THE FEMALE.

Anne M'Manus, *æt.* 60, unmarried, was admitted to St. Francis's Hospital, September 22, 1879. Has always been in delicate health. Two and a half years ago she had an attack of renal colic, which lasted nearly four hours. Shortly after this she began to

complain of a lancinating pain in the hypogastrum, frequent desire to micturate, and pain also about the meatus urinarius. For two years past she has been unable to pass her water. It had to be drawn off with a catheter. The catheter for some months previous to admission had to be passed fifteen times each day. The pain was constant, and received little or no relief from the catheterization.

On examination, patient was found to be pale and very much emaciated. The urine was alkaline on reaction, contained pus and mucus, and phosphates. On passing the sound, a calculus was found occupying the roof of the bladder near the neck. She was unable, or at least seemed to be unable, to pass her water under any circumstance.

On the 26th of September patient was etherized, and the neck of the bladder dilated with Molesworth's dilator, and two calculi extracted. The larger one was held in position by a layer of false membrane.

After operation, ten minims of morphia were injected, and ten grains of quinine given by the stomach.

Sept. 27th.—Pain in hypogastric region is diminished, but not completely absent. Pulse and temperature normal. Urine dribbles freely from the meatus.

Sept. 28th.—No pain in bladder; considerable pain at meatus urinarius, which is much swollen. Incontinence has ceased, and can pass water without any difficulty.

Sept. 29th.—Complains of pain and inability to make water. Catheter is again used.

Sept. 30th.—Patient able to go about; feels comfortable. Pus and mucus in very small quantities in the urine, but she insists on having the catheter used every three or four hours. Thinking that there was a little nymphomania evident in this, I ordered the catheter to be discontinued. For two days she passed water, but on the third day prevailed on the nurse to use it again, in order, as she said, to relieve her pain, and until she left the hospital I allowed its use two or three times each day, although I felt convinced that she could do without it, and that it was simply a desire for titillation which created a demand for its use.

It is a curious fact that the incontinence did not continue for some days longer in this case. Usually, after dilatation of the female urethra, there is incontinence for at least one week. In this case it lasted only twenty-four hours.

Unless the stone is very large, I think the lithectasy, if performed by means of Molesworth's dilator, is the best operation. The urethra can be stretched for an inch and a quarter without any danger of permanent incontinence, and in a few days resumes its normal size and function. The dilation of the urethra also serves another purpose, viz., cure of the cystitis. I have performed it for that disease alone with good results, and the cystitis due to the stone is much more rapidly removed than when crushing is resorted to.

WAXY DEGENERATION OF THE PLACENTA.

Dr. HEIFZMANN presented some specimens of placenta, with a view of supplementing a previous report upon the real character of the so-called fatty degeneration of that organ. He had concluded, from a number of specimens examined, that the deposit was waxy in character. His reasons for such opinion are given in a detailed written report.

This subject had been worked up in his laboratory by Dr. Jeannette B. Greene, resident physician in the House of Mercy. Ten placentae were examined, the youngest six weeks, the oldest eight months,

most of which were thought to be fatty when looked at with the naked eye. In eight cases the fetuses were born dead, or died shortly after delivery. The waxy degeneration was located both in the decidua portion and the villosities, only in three cases there being present a relatively trifling fatty degeneration of the decidua-elements. The nutrition of the fetus is interfered with by compression of the blood-vessels in the villosities, and in certain territories all vessels become impermeable to blood-corpuscles. The following reagents were applied: carmine, oil of cloves, turpentine, iodine, fuchsin, and methylanilin. It was shown that the waxy degeneration attacked the basis substance and killed the living matter only in the highest degrees of the disease, while the fatty degeneration takes place in the living reticulum of the protoplasm, mainly in the decidua-elements. In one case there was waxy degeneration of the amnios; in two cases waxy degeneration of the umbilical cord.

THE MICROSCOPICAL EXAMINATION OF THE SKIN IN A CASE OF ERYSIPELAS.

Dr. AMIDON presented microscopic specimens of idiopathic erysipelas as contributions to the study of the pathological anatomy of that affection.

An exceedingly violent facial erysipelas attacked a patient convalescing from acute articular rheumatism, and, complicated by a croupous pneumonia, proved fatal on the fifth day. The pulse ranged from 80 to 140, the respiration from 28 to 60, and the temperature from 39.5° C. to 40.6° C. Besides the visceral changes usually found in this disease, a minute examination of the skin (taken from the inflamed area) showed the following lesions: desquamation of the epidermis; rete mucosum everywhere thin, and in places separated from the subjacent papillae and disintegrated. The hair-follicles, sebaceous and sudoriferous glands the seat of abnormally large collections of young epithelial cells; many of the large and small blood-vessels are thrombosed, and all along their course a moderate, and in spots an excessive, migration of new cells has taken place. The subcutaneous cellular tissue everywhere contains an increased number of nuclei, especially marked in the adipose tissue. Here and there disorganized, sloughy masses are met in the subcutaneous areolar tissue, almost miliary in size. The subjacent muscle (in this case platysma) was the seat of a waxy change.

DROPSY CELL-FORMATION.

Dr. SEGUIN presented an example of very rare elemental disease of the nervous system, consisting of several ganglionic cells which had undergone the vacuole or dropsy cell-formation. The specimen was a section of the spinal cord below the point of softening of a case of descending degeneration of the lateral portions of the posterior columns. He remarked that the lesion had been observed by very few, and its pathological significance was at present unknown. These vacuoles presented the appearance of transparent circles, in some cases overlapping each other, seemingly embedded in the substance of the ganglionic cell. By some observers they were thought to have no pathological importance, being simply accidental appearances. Charcot, for instance, was inclined to believe them to be the results of decomposition.

THE PATHOLOGICAL DIFFERENCES OF DIPHTHERIA AND MEMBRANOUS CROUP.

Dr. LEWIS SMITH presented the larynx and trachea removed from an infant one and a half years old, who

had died of diphtheria a few days after the attack. The patient had been seized with hoarseness, followed by croupy cough and the usual attendant symptoms. No pseudo-membrane was visible in the fauces.

At the autopsy this exudation was discovered on the posterior surface of the uvula and along the adjacent sides. Dr. Smith exhibited the specimen for the sake of calling attention to the question of the diagnosis between diphtheria and croup. Clinically he could make out no distinction between the two, except that one was contagious, and the other not.

DR. HEITZMANN stated that four years ago he had the opportunity of examining many specimens of pseudo-membrane and sputa removed from the throats of children dying of diphtheria and croup. Many of these specimens were sent to him by Dr. Lewis Smith. As the result of his microscopical observations he had come to the conclusion that croup and diphtheria, as far as the deposit was concerned, were essentially the same thing, the only difference being that in croup the pseudo-membrane coagulates upon the surface of the membrane, killing the superficial epithelium, while in diphtheria this exudation goes into the substance of the tissue. When the latter condition obtains, there is death of the deeper tissues, and subsequently the appearance of nests of micrococci. It could easily be seen that in the earlier stages the membrane could be peeled off, while in the later stages this was impossible. In the earlier stages of the deposit the presence of the nests of micrococci was impossible.

DR. CARPENTER asked if a diagnosis could be made on the presence or absence of micrococci.

DR. HEITZMANN believed that this could be done in the earlier stages of the deposit.

DR. RIPLEY remarked that he had examined seventy-five cases in which pseudo-membrane had existed in the fauces, and in all micrococci were present. Consequently, allowing the theory advanced by Dr. H. to be the correct one, all the cases were those of diphtheria. Again, he had met with cases in which the membrane could be peeled from the underlying tissue, and yet these died of diphtheria with the usual symptoms of blood-poisoning.

DR. HEITZMANN stated that, in speaking of micrococci in diphtheria, he had purposely referred to their occurrence in nests. Otherwise there was no significance in their appearance, as it was well known that they were always more or less scattered in old ulcers.

ANEURISM OF THE ARCH OF THE AORTA.

DR. RIPLEY presented a specimen of aneurism of the arch of the aorta. The history was as follows:

F. M., German, *æt.* 34, waiter, was admitted into St. Francis's Hospital, Feb. 10, 1879. His family history could not be ascertained. He himself had had scarlet fever when a child, typhoid fever at seventeen, and subacute articular rheumatism eight years ago. He had also had several attacks of gonorrhœa, and five years ago syphilis. His present illness began several weeks ago, when, after exposure to cold, he began to suffer from pains in both scapular regions, the left hip, and left side. To these symptoms were added a dry cough and slight dyspnoea on exertion.

As the history book does not show that a general physical examination was made at this time, I presume it was not down, although a double aortic murmur is recorded. His troubles, for the most part, were attributed to constitutional syphilis, and after remaining in the hospital six weeks under treatment for that disease, he had so far recovered as to be able to resume work, and complained only of hoarseness,

which had been present during most of the time he was in the hospital. He continued at his business until the following September—four months—when he became a patient at the hospital. On admission he stated that he had not been free from hoarseness while away, and had periodic attacks of cough and dyspnoea. His subjective symptoms now were weakness, paroxysmal cough, and dyspnoea on exertion, and pain in the left shoulder, left side, and the left interscapular regions. He was aphonic, and had a harsh laryngeal cough, accompanied with abundant muco-purulent expectoration. Rest and sedatives relieved his distressing symptoms for a time, and my attention was not called to him until the middle of October, when notes were made of the following physical signs:

On inspection, deficient expansion was observed under both clavicles, most marked under the right; also epigastric and intercostal retraction during inspiration, most marked on the left side. By palpation the apex of the heart was found beating feebly in its normal position. No abnormal impulse could be felt at any point over the chest-walls. The left radial pulse was much smaller and feebler than the right, while pulsation in the left common carotid was stronger and fuller than in its fellow. Percussion under the right clavicle was vesiculo-tympanitic; in the left infra-clavicular region it was very dull, more marked nearer the sternum. The inspiration was broncho-vesicular under the right clavicle, and the expiration prolonged and wheezy. On the left side, in the same region, the inspiration was bronchial, while nothing but converged laryngeal sounds could be heard on expiration. Below these regions sibilant and sonorous râles accompanied a feeble respiratory murmur. Behind, in both interscapular regions, there was dullness on percussion, but more extensive and pronounced on the left side. Below, over both lungs, the percussion was tympanitic. The respiration in the right interscapular region was broncho-vesicular, accompanied with dry râles; and in the same region, on the left, it was purely bronchial. Below, over both lungs, exaggerated breathing.

The diagnosis of an intra-thoracic tumor was made, with, of course, the probabilities favoring aneurism. The case was referred to Dr. Elsberg for a laryngoscopic examination, who reported that he found "congestion of the soft parts in the interior of the larynx, and complete paralysis of the left vocal cord." After hearing the history, he expressed the opinion that the symptoms were due to aneurism. A few days later, I detected a slight diastolic murmur, heard only over a very circumscribed space in the median line near the fourth costo-sternal articulation. A positive diagnosis was now made of any aneurism of the transverse portion of the neck of the aorta pressing upon the left bronchus and trachea.

The further progress of the case presented few new features. The cough and dyspnoea continued to be the most prominent symptoms, pain not being very constant nor very severe. The patient died of exhaustion, October 22d, after having passed a night of great suffering from continuous difficulty of breathing.

The autopsy was made twenty-four hours after death, by Drs. Schlereth and Caldwell, of the house staff. After removing the sternum it was observed that the lungs had not collapsed, but that the parts visible were in a state of extreme inflation and bloodless. There was no fluid in the pleural cavity. The middle lobe of the right lung, and the lower lobe of the left lung were firmly attached to the costal

pleura, by old inflammatory bands. The lungs still remained distended after removal from the chest, and were comparatively bloodless, except their lower lobes, which were the seat of hypostatic congestion and œdema. Several subpleural air-bulbs were noticed in either lung, and the superficial vesicles generally appeared larger than normal. The larger bronchi, especially of the left lung, were filled with muco-pus, and the mucous membrane inflamed. The heart and great vessels, the larynx, trachea, and the stumps of the primary bronchi and the œsophagus, were removed *en masse*. An examination of these organs showed a sacculated aneurism the size of a large Havana orange springing from the posterior and superior wall of the transverse portion of the arch of the aorta, and including in its pouch the origins of the left common carotid and the left subclavian arteries. It had rested upon the left side of the body of the third dorsal vertebra, which, denuded of its periosteum and partially absorbed, had formed the posterior wall of the tumor. It had also forced its expansion downward into the left broncho-tracheal angle, so as to flatten and partly close both of these tubes. The left inferior laryngeal nerve was pressed upon throughout nearly its entire length, and was with difficulty dissected out for examination. The ascending part of the arch was noticeably dilated and atheromatous. The heart presented no marked pathological changes. The mucous membrane of the interior of the larynx above the vocal cords was congested and a little thickened. The liver and kidneys were congested. Traces of an old perisplenitis were found, and the organ itself was enlarged. The other organs were not examined.

The points which seem to me of most interest in this case are:

1. The inflated and emphysematous condition of the lungs.
2. The absence of any marked hypertrophy of the left ventricle of the heart.
3. The presence of a diastolic murmur alone.
4. The mechanical paralysis of the recurrent nerve.

The state of the lungs was of especial interest to me because it corresponded, substantially, to that in which I have found those of children who have died of bronchial croup after tracheotomy, and due, practically, to the same cause—narrowing of the air-passages. In a majority of these cases, the children die in from about sixty to eighty hours after the operation. The cough increases, the pulse and respirations become accelerated, and the temperature rises to 103°-105°. Nearly the same physical signs are present as before the operation. An autopsy shows inflated and anæmic lungs, while here and there a patch of collapsed membrane lines the tubes to a variable extent, completely plugging those branches leading to collapsed lobules. I have never yet found pneumonia at such autopsies, although it is put down in the text-books generally as the most frequent cause of death.

OVARIAN CYST AND CYST OF BROAD LIGAMENT.

DR. C. C. LEE exhibited two specimens, one consisting of a large ovarian cyst, and another of a cyst of the broad ligament, for the purpose of comparing the pathological appearances of each. The ovarian cyst had been removed by him ten days before, and contained twenty pounds of albuminous ovarian fluid. Notwithstanding it had been growing for ten years, not a single adhesion was present.

The second specimen, that of cyst of the broad ligament, was removed by Dr. Emmet. It contained

clear fluid, non-albuminous in character, and of a low specific gravity, and contained none of the ovarian corpuscles.

Dr. Lee called attention to the differences in the physical appearances of the two specimens. The ovarian cyst was smooth, and showed no veins upon its surface, while the cyst of the broad ligament presented the appearance of a fibro-cystic growth covered with veins.

The diagnosis between these two growths was not very easy before operation. Still it was well to take into account the extreme rarity of cysts of the broad ligament compared with ovarian tumors, their comparatively slow growth, and the small amount of constitutional disturbance which they caused. The character of the fluid would be of assistance in arriving at an opinion, inasmuch as said fluid was not albuminous and did not contain the characteristic ovarian corpuscle.

RAPID LITHOTRITY—DEATH.

DR. KEYES presented specimens of five urinary calculi removed from five old men averaging over sixty-six years of age.

The largest stone weighed 540 grains, and was removed by Thompson's washing-bottle in fifty-seven minutes, all told. The smallest stone weighed ninety-eight grains dry. It was removed in nineteen minutes.

Dr. Keyes used his own modification of the lithotrite for crushing the stone in every case.

Thompson's newest improvement in the washing-bottle was exhibited. It was used in Dr. Keyes's last case.

These stones made a series of twenty consecutive operations of rapid lithotripsy performed by Dr. Keyes in connection with Dr. Van Buren.

There had occurred one death. It was the fourth of the last five of the series. The bladder and kidneys were shown.

This patient was a gentleman of sixty-seven. He was known to have pyelitis and kidney disease before the operation. His urine was very light, and contained casts and albumen besides the pus.

The patient had been confined to bed by his malady nine months. The stone had not been discovered.

Dr. Keyes concluded to attempt rapid lithotripsy as being the only operation offering the patient any chance.

The bladder was pouched toward the right ureter. Thirteen minutes were consumed in catching the stone for the first time, and a seizure was only finally effected by turning the patient well upon the side.

After one hour of manipulation, rendered very unsatisfactory by the pouched condition of the bladder, the sitting was terminated; one hundred and ninety grains were removed. No chill or serious consequence followed, and it was decided, after three weeks, to undertake another sitting.

The second sitting lasted one hour. Débris, weighing when dry twenty-eight grains, required one hour for their removal, it being next to impossible to get the last fragments out of the pouch. An increase in the quantity of pus in the urine followed with almost total suppression, and death on the fifth day.

The right kidney was shown of about one-half its normal size, and the seat of interstitial nephritis. The left kidney was of full size, but similarly diseased, although to a less extent. Each kidney pelvis contained about a gill of thick pus, the left one some

fragments of phosphatic stone. Both ureters were thickened and dilated.

The urethra was healthy. The prostate was the seat of some central enlargement.

The bladder was smooth and uncongested. It showed no evidence of violence. The mucous membrane was unbroken. The pouch at the site of the entrance of the right ureter into the bladder was very evident.

The walls of the bladder were much thickened.

Dr. Keyes maintained in this case that the patient's diseased condition was the cause of death, a catastrophe precipitated undoubtedly by the operation. He still believed, however, that the latter was justifiable under the peculiar circumstances of the case.

In one very similar case, the same operation had been entirely successful at his hands.

In the present instance, as shown by post-mortem examination, the operative manoeuvres had not resulted in any direct physical lesions.

Referring, in one of the cases, to the difficulty of grasping the stone in the bladder, Dr. Lee suggested that the stone might have been fixed by grasping the base of the bladder by the hand previously introduced into the rectum. Dr. Lee had succeeded in fixing the uterus in that manner when all other means had failed. The case was one of retained placenta with flooding.

Dr. Keyes remarked that there was less risk in resorting to such a manoeuvre in the female than in the male, the pelvis of the former being much more roomy.

The Society then went into Executive Session.

Correspondence.

RESUSCITATION OF AN INFANT AFTER A LONG PERIOD OF ASPHYXIA.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: A recent number of your journal contains an article giving an account of the resuscitation of a new-born infant after a very long period of asphyxia. A case occurring in my own practice a short time ago may be of interest in this connection.

Mary D—, an Italian woman, 18 years of age, was taken in labor Nov. 4th, at 9 o'clock P.M. I saw her soon after, and found the os partly dilated and the child presenting by the breech.

I informed the friends of the girl that, owing to the mother being a primipara and rather small, there would be some danger to the child in this case, though little or none to the mother. At 12 P.M. the os was fully dilated, but the pains were infrequent and the child made no advance. After waiting a long time, I disengaged one leg and brought it down in the vagina. At the end of another hour, the child making no advance and the woman showing some signs of exhaustion, I was compelled to make traction upon the child's foot to hasten the delivery. In thirty minutes the shoulders were born, and the arms safely brought down by the side. I then instructed the husband to make firm pressure upon the abdomen over the fundus of the uterus, while I encouraged the mother to make strong bearing-down efforts. The head soon came down so that I could insert two fingers of my left hand into the child's

mouth, while my right hand grasped the back of the child's neck under the pulvic arch. This was the critical moment for the child, but unfortunately, owing to the rigidity of the mother's parts, no progress could be made for some time, and, in despite of every effort on my part, it was fully five minutes before the head was born.

The English authorities state that, if the head is delayed in the passages longer than three minutes after the birth of the shoulders, the result to the child is almost invariably fatal. In consequence of the long delay in the delivery of the head, I was not surprised to find the child asphyxiated. The cord did not pulsate, nor did it bleed when cut. My finger, when passed into the child's mouth and down into the larynx, could not detect the faintest sign of any reflex action. To all appearances, except for a faint and infrequent pulsation of the heart, the child was limp and dead.

I at once laid the child upon blankets before the fire, and commenced artificial respiration according to Marshall Hall's method. After some fifteen minutes at this method, combined with dipping the child alternately into hot and cold water and rubbing with brandy, there was no sign of animation. I then resorted to another method of artificial respiration. Holding the back of the head and shoulders in my left hand and the pelvis in my right, with the little fingers of each hand extending along the spine, I alternately flexed and extended the body of the child, after the manner of opening and closing a jack-knife. By this means I attempted to contract and expand the cavity of the thorax. A prolonged effort by this method gave no apparent result, and I resorted to a third.

The child was placed in a sitting posture upon blankets before the fire. My right hand was placed behind the head and thorax of the child, and its body leaned backward so that it rested upon this hand. The hands of the child were carried as far as possible above its head by my left hand. By this the ribs and shoulders were raised, while the head was thrown backward, thus expanding the thorax and drawing air into the lungs. The second movement was to lower the arms of the child so that they fell by its side, while my hand, still retaining those of the child in its grasp, rested against the front of the child's thorax and head. The third movement was to lean the child forward and press suddenly downward upon its shoulders, at the same time that the hand in front pressed the ribs inward. This method, which is somewhat difficult to describe, but easy to carry out, caused the first certain expulsion of air from the child's lungs (and a consequent re-filling of them), for the air could be heard bubbling out through the nose and mouth of the child. Then the lungs were re-filled by the first movement. Still this respiration was entirely involuntary on the part of the child, and ten minutes' persistent effort by this method gave no sign of returning animation. Nearly three-quarters of an hour had now elapsed since the birth of the child, and meantime the child's skin began to feel cold and clammy. On account of the coldness of the child, I determined to use external heat in conjunction with artificial respiration. I called for a deep bowl partly filled with water, at a temperature of about 112°. I placed the child in the bowl in a sitting posture, so that the water came up to the child's diaphragm when its body was in what I have called the "first position" in the last method of artificial respiration.

Then the artificial respiration was kept up accord-

ing to this method, while the child's body was partly immersed in hot water. After a few minutes, I was astonished at the child showing a little color in its cheeks, and then making its first spasmodic effort at inspiration. Fully five minutes elapsed before it made another gasp, but gradually its efforts became more frequent, and at the end of an hour and three-quarters from the time of its birth, I ventured to cease artificial respiration. The child was then breathing rapidly with a shallow gasping respiration. I ordered it to be rolled in blankets, without being dressed, and placed in the bed with its mother. Two hours later its breathing was stronger, but still shallow. The following day it appeared as strong as any child, and since then has grown rapidly.

I wish to call attention to a few points in this case.

First.—The long period of profound asphyxia. It was more than three-quarters of an hour before the child gave the faintest sign of returning animation. The asphyxia was so profound, that during all this time, when my finger was carried down into the child's larynx, so as to touch its vocal cords, there was not the slightest indication of reflex action. Hence, I judged that external stimuli, such as slapping and dipping into alternately hot and cold water, would have but little effect in this case. There have been cases of longer asphyxia of the new-born than this reported, but I venture to say that many infants are allowed to perish, because less persistent efforts on the part of the accoucheur are made than were made in this case.

Second.—This method of artificial respiration, with the child in the sitting posture, as I have described it on a former page, is in my judgment more efficient than any other method of artificial respiration for the new-born.

The defect in the Marshall Hall method of artificial respiration is, that while the thorax is being compressed to cause expulsion of the air from the lungs, the diaphragm is apt to be pushed downward, thus partly annulling the effect. In the method of respiration by flexing and extending the body of the child, the arms of the child are not raised above its head during the attempts at expanding the thorax, hence the fullest expansion is not attained.

But in the method with the child in the sitting posture, the arms of the child are carried above its head during the attempts at filling the lungs, while in the expiratory effort the diaphragm is pushed strongly upward at the same instant that the ribs are pressed inward.

Third.—This method of artificial respiration is the only one that can be conveniently used while the body of the child is partly immersed in hot water; that is, *the only method that can be used while a high degree of external heat is closely and constantly applied to the subject.*

Fourth.—The value of external heat in asphyxia neonatorum.

It has come to be a recognized fact that external heat is of great value in restoring animation in cases of drowning or fainting. It should not be of less importance in asphyxia of the new-born. In a profound case of asphyxia neonatorum, the continuance of the asphyxia is not due to the absence of respiration alone—for, by a good method of artificial respiration, we can perform this function, so far as regularly supplying the lungs with air is concerned; but it is due to the weak and deficient circulation of the blood. As a consequence, the nerve centres do not receive the stimulus of oxygen, and the respiratory

and other functions are not established. Hence, the indication is to supply a strong stimulant to the circulation. Such a stimulant is *external heat*, and practically it is the only stimulant that can be employed in these cases.

Not alone does external heat act as a stimulant to the circulation, but it prevents that rapid waste of animal heat that must ensue where the usual methods of artificial respiration are employed.

Without laying claim to originality in the use of external heat alone in the resuscitation of the new-born, or of artificial respiration alone, yet, so far as I know, this is the first case reported where a high degree of external heat and an efficient method of artificial respiration have been combined in the same method of resuscitation.

W. E. FOREST, M.D.

168 SPRING STREET, DEC. 8, 1879.

GRATUITOUS SERVICES TO CLERGYMEN.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In a recent editorial you alluded to the custom of "deadheading" clergymen, and suggested that the medical profession owed them little consideration, on the ground that they (the clergymen) were among the strongest upholders and abettors of quackery, and exerted their influence against the welfare of the profession far more frequently than in favor of it. A striking instance of this appeared in this morning's paper, announcing the formation of another Twenty-five Cent. Provident Dispensary, which, the newspaper informs us, is recommended by the Rev. Dr. Crosby, the Rev. Dr. Ormiston, the Rev. Dr. Collyer, Bishop Potter, and the Rev. Dr. Taylor. Do these gentlemen really suppose that the enterprise is conceived in a spirit of pure charity? Do they not know that the "provident" feature is rather calculated to provide a comfortable living for an impecunious doctor, than to create a feeling of independence among the poorer classes, and help the general profession? We are glad to find that the name of the physician in charge of this new Provident Dispensary is not in the Medical Register.

Yours respectfully,

M. D.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 7th to December 13th, 1879.

KIMBALL, J. P., Capt. and Asst. Surgeon. When relieved from duty at White River, Colo., to proceed to Ft. Sanders, Wv. T., and resume his duties as Post Surgeon. S. O. 111, Dept. of the Platte, Dec. 6, 1879.

DEWITT, C., Capt. and Asst. Surgeon. To resume his duties as Post Surgeon, Fort Sidney, Neb. S. O. 111, C. S., Dept. of the Platte.

BENGAL BRANCH OF THE BRITISH MEDICAL ASSOCIATION.—An Indian branch of the British Medical Association was founded several years ago, but has not held any annual meetings for a considerable time. It is now to be revived, and made an active organization again.

SUITS FOR MALPRACTICE.—At a regular meeting of the Baltimore Medical and Surgical Society, the following preamble and resolutions were unanimously adopted:

"Whereas, There have occurred of late several instances of unjust and unwarrantable prosecutions of members of the medical profession for alleged malpractice, with the evident intention of mulcting them for damages, we deem it advisable, for the protection of the profession, to urge upon them not to lend aid or countenance to such efforts by unguarded expressions of opinions; and therefore be it—

"Resolved, by the Medical and Surgical Society of Baltimore, That as physicians and surgeons we will not aid, abet, or encourage any proceeding favoring suits for malpractice against members of our profession who are in good standing.

"Resolved, That we will uphold the dignity and honor of the profession under all circumstances, and support and sustain its members when shadowed by unjust demands or assailed by unworthy asseverations."—*Virginia Med. Monthly*.

AMERICAN MEDICAL ASSOCIATION.—At a meeting of the Committee of Arrangements of the American Medical Association, held in this city Dec. 3, 1879, the following committees were appointed: *Committee on Building*—Drs. M. A. Pallen, M. H. Burton, W. M. Polk. *Reception Committee*—Drs. Jos. C. Hutchinson, W. M. Polk, M. A. Pallen. *Committee on Finance*—Drs. Stephen Smith, A. A. Smith, W. R. Gillette, R. F. Weir, M. H. Burton, E. H. Parker. *Committee on Business*—Drs. M. A. Pallen, Jos. C. Hutchinson, Stephen Smith. *Committee on Invitations*—Drs. W. M. Polk, R. F. Weir, E. H. Parker. *Committee on Entertainment*—Drs. C. J. Pardee, M. A. Pallen, F. Weir. *Committee on Printing*—Drs. R. F. Weir, Stephen Smith, W. R. Gillette. S. O. Vander Poel, M.D., Chairman Committee of Arrangements; W. R. Gillette, M.D., Secretary Committee of Arrangements.

DR. ALFRED H. McCLESTOCK, the eminent Dublin obstetrician, is expected to reach this city early in the coming January.

DR. JOHN L. ATLEE, OF PENNSYLVANIA.—Dr. J. Marion Sims gave a reception on Friday evening, December 12th, at his residence on Madison Avenue, in honor of Dr. John L. Atlee, of Lancaster, Penn., who made a short visit to this city. The attendance was large, and represented the medical celebrities of this and neighboring cities. Dr. Sims made an appropriate speech, which he concluded by reading a letter of regret from Prof. Gross, of Philadelphia. ;

Dr. Atlee responded, and humorously referred to the telling qualities of the Dutch blood of Pennsylvania. He also took occasion to say that the courses of instruction in the medical colleges were too brief. The effectiveness of this part of the speech was well-nigh destroyed by a playful remark of Dr. Sims, to the effect that both himself and Dr. Atlee took only two courses of lectures. But Dr. Atlee was equal to the occasion by the remark, "We could learn more then than students can now."

A bountiful supper was afterwards served, and the remainder of the evening was spent in pleasant social intercourse.

Among the gentlemen present were Professors Barker, Darling, Draper, Gouley, Hammond, Hamilton, Keyes, Lusk, Loomis, McCready, Noyes, Otis, Pallen, Sayre, Seguin, Taylor, Thomson, Wood, and Doctors Anderson, Agnew, Clymer, Eliot, Garrigues, Gillette, Heitzman, May (of Washington), Nichols, G. P. Shradly, Charles D. Smith, and a host of representative young men in the profession.

There was a large delegation from Brooklyn amongst them: Armor, Bell, Burge, Dudley, and Hutchison. Also, Kimball, of Lowell; Swinburne, of Albany; Didama, of Syracuse; Fisher, of Sing Sing; Vedder, of Jersey City; Levis and Goodell, of Philadelphia, and Bramlette, of Virginia.

NEW YORK MEDICAL JOURNAL.—Dr. James B. Hunter has resigned his position as editor of the *New York Medical Journal*. His successor is Dr. Frank P. Foster, of this city. Dr. Hunter has been for a long time connected with this journal, and has succeeded in placing it in the front rank of American monthlies. From what we know of the ability and industry of Dr. Foster, the new editor, we have no doubt that the high reputation of the periodical will be maintained. We cordially wish him abundant success.

JOURNALISTIC CHANGES.—The *Medical News and Library*, and the *Monthly Abstract of Medical Science*, have been consolidated into a single issue—*The Medical News and Abstract*. The "library" department of the *News* has been given up and the clinical department enlarged.

HONORS TO DR. J. LAWRENCE SMITH.—Professor Smith, who has, in addition to many other honors, recently been made Corresponding Member of the Institute of France, was tendered a complimentary dinner by the citizens of Louisville on his return to that city. A number of toasts were given and speeches made. Among others a toast to "The Press" was responded to by Dr. R. O. Cowling, of the *Louisville Medical News*, who, in a very clever speech, maintained that the *L. M. News* was the only independent political journal in the city.

PROF. GEORGE E. POST, M.D., BEIRUT, SYRIA.—We are gratified to learn that our countryman, Professor George E. Post, M.D., has been knighted by the Prussian Government, and has received the decoration of the "Ernestine Hausorden of Saxony," on account of his services in the Hospital of St. John, under the charge of the Prussian deaconesses at Beirut, Syria.

SALISBURY PLAN OF TREATMENT OF CONSUMPTION.—Dr. Ephraim Cutter has established a small "home" near Boston, for carrying out the Salisbury treatment of consumption. Dr. S., we believe, claims to diagnose consumption one year before the development of its usual symptoms and signs. This is done by

examining the blood, which, in the protuberentous state, contains certain spores and fibrin filaments. The method of cure is by a rigid system of diet, raw meat being a prominent feature of the same.—*Va. Med. Monthly.*

PAINLESS LABOR.—Dr. William Badger, of Flushing, N. Y., writes: "In your issue of November 22d, is an article with above caption, by Dr. A. M. Smith, which encourages me to relate the following particulars, which I have refrained from publishing earlier, fearing it might appear slightly fishy:

"In the spring of 1875 I was engaged by Mrs. F. to attend her in her fourth confinement; she requesting me to go as speedily as might be when called, as she 'had never had any pain in her previous labors, and consequently could not know how early to send.'

"On the morning of April 20th I received the expected summons. While removing my overcoat she exclaimed, 'Hurry, doctor, I fear you are almost too late.' I replied, 'You do not appear to be in pain.' She answered, 'I have no pain, but I know it is coming.' I found the head upon the perineum, and the delivery was completed by two strong expulsive uterine efforts; but, as she assured me, without pain, and her countenance and manner were not indicative of the slightest suffering.

"She had no after-pains—said she had never had any—and was up on the fourth day.

"In subsequent conversations, she again assured me that in her four confinements she had had no labor pains."

IN THE HIGHER WALKS OF CHEMISTRY.—At a late meeting of the Section of Chemistry of the New York Academy of Sciences, a paper was read with the following title:

"Some New Azo-compounds: including Azobenzol-trinitro-oxybenzol, Azobenzol-trioxybenzol, Azobenzol-oxycarboxylbenzol, Azosulphoxybenzol-phlogluen, Diamidoazo-toluol, Diamidoazo-naphthaline-hydrochlorate, and Azobenzol-methylsulphoxybenzol"—(with specimens).

This shows progress, and gives us hope that many of the hidden things may yet be revealed unto us. Possibly some of these compounds would be of service in diphtheria, by being effective bactericidic. For most horses, the hay is a little beyond reach, but to the few who are accustomed to feed from high levels, rare opportunities are now offered. The Diamidoazo-naphthaline-hydrochlorate would seem to give the best promises for further study. We venture this opinion without having seen the specimen. At all events, we are pleased to learn that our chemical friends are still adding to our stock of knowledge, and helping to make their science an exact one.

THE DOCTOR'S FEE AND THE WAY OF THE WORLD.—Patient with severe colicky pains at 3 A.M., says to his doctor:

"Save me, and I will give you a check for a thousand dollars."

As patient is wealthy, doctor smiles "childlike and bland," and administers an hypodermic injection of morphine.

Five minutes have elapsed, and patient feels easier.

"Keep at it, doctor, and I will give you a check for five hundred dollars."

Five minutes more, and patient drowsily turns in his bed, smiles his thankfulness through his tears, and assures the doctor that he feels like giving him a "fif-t-y dol-lar bi-ll."

The doctor calls the following day, finds his patient up and dressed, and ready to go to his business.

"You see, doctor, I have got over my little attack without giving you much trouble, but be sure to send in your bill the first of the month."

When six months elapsed the doctor sent in a bill amounting to three dollars. His grateful patient pressed him to cut it down to two. After so doing, the doctor sued to get it, and his patient put in a stay of execution. Case still on.

The doctor has lost his faith in grateful humanity, has moved to Pine Ridge, on the Hudson, and is negotiating for a partnership with the "Successful Practitioner."

THE LATE DR. OLIVER WHITE, OF NEW YORK.—At a meeting of the Medical Board of the Presbyterian Hospital, held Nov. 12, 1879, Drs. William Detmold, Jared Linsly, and Gouverneur M. Smith were appointed a committee to prepare resolutions in relation to the decease of Dr. Oliver White, which resolutions we herewith respectfully submit.

Whereas, Dr. Oliver White, an earnest friend of the Presbyterian Hospital from its incipency, and for a number of years President of the Medical Board, has been removed by death:

Resolved, That the Medical Board desires to express and to place on record its warm appreciation of the loss the hospital has sustained by this bereavement.

Resolved, That Dr. White, during the inception of the hospital, and before it was erected, interested himself in promoting the success of the benevolent enterprise, and in engaging both the influence and means of a number of the medical profession in promoting the humane purpose of the institution.

Resolved, That Dr. White, to the close of life, was unremitting in his interests in the hospital, and, when smitten with disease, persisted in performing his duties until overwhelmed by his malady.

Resolved, That as Consulting Physician and as President of the Medical Board, his counsels were wise, being governed by intellectual vigor and Christian principle, and that the successful career of the hospital has been due in no small measure to his watchfulness and guidance.

Resolved, That a copy of the above preamble and resolutions be sent to the family of the deceased, to the Board of Managers of the Hospital, be recorded on the minutes of the Medical Board, and be published in the medical journals.

S. T. HUBBARD, *Chairman.*

JAMES V. S. WOOLLEY, *Secretary.*

SOME OF THE

COMMONER AFFECTIONS OF THE TONSILS, FROM A DIAGNOSTIC AND THERAPEUTIC STANDPOINT.*

By GEORGE M. LEFFERTS, M.D.,

CLINICAL PROFESSOR OF LARYNGOSCOPY AND DISEASES OF THE THROAT, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

MR. PRESIDENT AND GENTLEMEN:—Pleasurable as it is to me to try and serve the Academy of Medicine, it is not without some hesitation that I stand here to-night, in the fear that I may be accused of an undue and immodest assumption of authority upon the special topics to which I shall, for a few moments, ask your attention. I reassure myself, however, with the reflection that our objects and aims are ultimately the same, and that the general practitioner and the specialist, each in his own department of work, and according to the opportunities granted him, strives to relieve the suffering, to minister to the comfort of man's estate, and to lessen the sum of human sorrow upon earth; and still further, as Hutchinson has told us, "that in the early stage of any department of knowledge, it is almost a matter of necessity that it should be in the hands of a few; but it is the highest privilege of those who thus devote themselves to reclaiming new spots of territory, to be able, after a time, to hand them over to the commonwealth, to prove that they are now cultivated and well worthy of annexation."

Our work is therefore inseparable. We must, of necessity, look to each other for assistance; each is able to contribute from his store of experience—an experience gained by earnest, manly labor in that particular field to which inclination, opportunity, or special paths of study have led him—something which will be of value to his fellows,—the elder to the younger, the younger specialist to the older practitioner.

With these views, and in this spirit, I have selected for your consideration and discussion, at the suggestion of our honored President, a topic which is taken from that special field in which I am a worker, and which I believe can be made of practical interest to both of us.

Although it is not long since laryngology has taken its place with medicine and surgery as a special study, it has, in that short time, shown in all its departments a great and rapid progress. It to-day contains much that is new and valuable. More ample and more accurate are the means at our disposal for diagnosis in affections of the upper air-passages; more extensive and more detailed is our knowledge of the healthy and morbid changes which take place in the larynx, and in the enunciation of its pathological laws. New remedial agents have been discovered, and old ones more scientifically used. Means have been rejected which are proven to be inert and useless, though transmitted to us surrounded by the halo of age and tradition. A broader view is taken of the treatment of many throat affections—notably of those of which I shall speak to-night. Routine and empirical treatment—the "do-something" therapeutics of Williams—have been dis-

carded; and finally, laryngeal surgery has been perfected, and endo-laryngeal means attained brilliant results—a perfection and results which almost tempt us to say, with Erichsen, "that we believe we have reached something like finality in the manipulative art of surgery."

I propose, then, asking your attention to some of these newer points in one branch of the art—that of the diagnosis and treatment of some of the commoner tonsillar affections; and, while I naturally strive to avoid an apparent position of didactic pretension, to which I cannot feel that I am entitled, to offer a few suggestions which may, perhaps, be profitably utilized by those in general practice.

Starting with the trite maxim, that before we can act, we should learn to see; to see in order to foresee; and to foresee in order to modify and direct, I desire to deprecate the old method of a tea-spoon handle and an imperfect and titful light, and to call the attention of the practitioner unfamiliar with its use to the valuable assistance rendered, in any pharyngeal examination, by the large and well-made concave forehead reflector of the laryngoscopist, and the use of artificial illumination. It renders him independent of time. Night is as day. It allows of his examining his patient in any position and in any place without disturbing him; the faces of the frightened child in its mother's lap, of the bedridden adult, of the patient unwilling or incapable of moving at the dictum of the surgeon, and of the sufferer unable to more than slightly unclose his jaws, can severally be quickly and thoroughly examined; while the extent and accuracy of the picture obtained will be such as to surprise the practitioner unversed in the use of these methods, and richly repay him for any time or trouble expended in unlearning old ways and acquiring new.

A tendency, which is to be deplored on diagnostic and therapeutic grounds, exists in the practice of many medical men to be less particular than it seems to me they should be in the *nomenclature* of tonsillar affections; to class all inflammatory diseases, whether within the tonsillar gland, or of the tissues in its immediate neighborhood, as one and a similar affection. "Quinsy and ulcerated sore throat" are terms which with them cover the whole ground; while, on the other hand, the public are too prone to speak of every throat affection as "diphtheritic," a conceit in which, I regret to say, they are encouraged by a certain class of practitioners.

This looseness of nomenclature can but lead to confusion, misconception, and unscientific treatment. As a matter of fact, the inflammatory conditions to be named, both in their causation, seat, symptomatology and treatment, are as widely different as in like conditions elsewhere. And it does not appear to me, therefore, that the differences of which I shall speak can be said to be only of amount and degree, and that they involve no true pathological variety, as has been asserted.

Inflammation may attack either the parenchymatous tissue, or the secreting tissue of the tonsil, or the tissues about it. This is our classification. In the former case, if acute, it will proceed to the formation of true tonsillar abscess, or so-called quinsy; but let me state at once, that such a condition is comparatively rare, and that abscess of the tonsil, so regarded, is more often an inflammation and suppuration of the tissues at the base or in front of the gland, but with all the distressing symptoms, and the same general appearances, as in the true affection. Verneuil has shown us that the tonsil does not ad-

* Paper read before the New York Academy of Medicine, Dec. 5, 1879.

here very firmly to the groove, if it may be so termed, which lies behind it; and that when tumefied by inflammation, it bulges out between the anterior and posterior pillars of the soft palate, and moves backward and forward with every movement of deglutition. This mobility, he asserts, is one of the principal causes of the formation of abscess. The gland being continually displaced, a serous bag forms in the connective tissue, which stretches between both pillars of the fauces, and occupies the bottom of the groove in which the tonsil lies. In this serous bag the purulent gathering is formed. Such an abscess—and bear in mind, if you please, that it is the one commonly met with in practice—is always deep-seated, and cannot, therefore, be easily reached by the knife, as an incision directed in a straight line toward and through the tumor, which the tonsil forms in the isthmus of the pharynx, would not be able, under ordinary circumstances, to open it.

The practical import of this observation is at once apparent. To incise such an abscess, it is necessary to cut through the anterior pillar of the fauces; for this pillar—enlarged, œdematous, and protruding—forms the anterior wall of the abscess. In this locality, even as high up as near the junction of the hard and soft palate, I have repeatedly operated with success, and, I must add, have in some instances experienced that mortification which every surgeon must feel who cuts for pus and does not obtain it. The reason, after one or two mistakes, was clear to me. The swelling of the tissues in the locality just described puts upon the stretch the musc. thyreo-palatinus, in the anterior arch of the soft palate; and the musc. pharyngo-palatinus, which lies to the outer side of it, in close relation to the tense lig. pterygo-mandibulare; between the two is thus left a small, triangular, soft spot, palpation of which conveys to the finger a decided sense of fluctuation, which is very deceptive. I therefore call your particular attention to it.

When the inflammation occurs in the secreting tissues of the tonsil, it rarely, if ever, on the other hand, develops an abscess, and its character may be more distinctly expressed by the terms tonsillar catarrh, acute catarrhal tonsillitis, follicular tonsillitis, or caseous tonsillitis, by Bouchut. Here we deal, pathologically, with an inflammation of the membrane lining the crypts of the tonsils—an ordinary affection, one met with in every-day practice, presenting to the eye the familiar appearance of enlarged, brightly reddened, and vascular tonsils, encroaching materially upon the faucial opening, perhaps occluding it, their crypts blocked up by a thickened, cheesy, and opaque secretion, and appearing upon the surface of the tonsil as disseminated spots of a white or yellow color. Add to these appearances a cutting soreness on deglutition, marked constitutional disturbance and prostration, with elevation of temperature and short duration, and the picture is complete. I have drawn it mainly to call your attention to some of the difficulties in the way of diagnosis which may meet us, in such cases, at the very outset.

The commonest mistake made is in terming the affection an "ulcerated sore throat," or an "ulceration of the tonsils;" and the collections of morbid secretion at the mouths of the crypts resembling, as closely as they do, little ulcerations, the mistake is perhaps a natural one. The term certainly has taken a strong hold upon the laity, and I may perhaps justly add, the profession, if we may judge from the frequency with which we hear of "ulcerated sore throats."

As a matter of fact, true ulceration of the tonsil is extremely rare, except in syphilis; and recognizing this fact, we are in a position, without hesitation, in the vast majority of cases of so-called "ulcerated throats," to pronounce, even without examination, in favor of a simple "catarrhal tonsillitis;" if we except the "herpetic tonsillitis" of recent French writers—an affection in which the tonsil is more or less covered with small vesicles, either isolated here and there, or in groups, with turbid contents and surrounded by zones of inflammation. Soon the vesicles rupture, leaving small excoriations—the so-called "ulcers." There can be no doubt as to the nature of the diagnosis, when, as occurs in many cases, a herpetic eruption occupies the corners of the mouth at the same time, or the inner surface of the lips, cheeks, or tongue.

The liability of confounding the milder pharyngeal manifestations of diphtheria—the "catarrhal diphtheritis" of Oertel—with the affection of which we are speaking is not to be overlooked; and that the danger is a real one, and one that needs to be provided for, is, I think, proven by the prevalence of—wrongly so-called—"diphtheritic sore throats." May I trespass upon your good-nature for one moment, while I allude to the, in many points, striking physical similarity of the two affections?

Have you not often seen, in these cases of follicular tonsillitis, an aggregation of the grayish-white pultaceous masses which block up the mouths of the diseased and occluded crypts to such an extent that not only is an apparent, but a real pseudo-membrane formed—one thickened by the products of cellular growth and decay (fungi and bacteria), and rendered coherent by the inflammatory hyperplasia?

A membrane which may occupy only part of the tonsillar surface appears here and there in patches, or, more rarely, still not infrequently, cover them entirely. The appearance is not an unusual one, and the attendant constitutional disturbance well known. Compare both with the description given by Oertel of the physical appearances in "catarrhal diphtheritis;" the results are interesting and instructive.

He tells us that the first thing noticed in the inspection of the mouth and fauces is "a vivid red color and moderate swelling of a part of the mucous membrane, while the rest of it appears perfectly normal. Frequently only one tonsil and the adjoining arch of the soft palate are attacked. The submucous tissue usually swells but little, and the same is true of the glands and tissues lying still deeper, so that while the enlarged tonsil may project somewhat into the isthmus, its volume is not increased, as is the case in parenchymatous inflammation. When this simple inflammatory process has continued for a short time—perhaps only a few hours—small grayish-white or whitish-yellow spots appear, arranged in a few groups, either separated from each other by a narrow space, or lying close together, sometimes even merging one into the other."

In the greater number of cases belonging to this class, the exudation is confined to one or the other tonsil, and only in rare instances gives rise to marked constitutional disturbance.

Oertel acknowledges, then, that the catarrhal form of diphtheria is generally recognized with difficulty, because of its apparently insignificant symptoms, and that other diseases, notably catarrhal angina, are frequently mistaken for it.

Appreciating the danger of confounding the two affections, the differential diagnosis may be made by the circumspect weighing of all the diagnostic

points—in one case danger of infection, in the other none—by a careful review of all the variations, in the general and subjective symptoms, especially a close ocular inspection, when the membrane will be seen in one case to be adherent to and upon, the surface of the tonsil, in the other non-adherent and made up of the yellowish, sticky mass which issues from the follicles. Again, the appearance of the parts when the exudation is removed, in the one case, with a slightly abraided surface beneath it; in the other, the mouths of the open follicles, into which the probe can be passed. *Finally*, a thorough physical examination, and a microscopical investigation as to the true nature of the membranous patches, if it be deemed necessary. But, even with this care, in sporadic cases a definite distinction is often extraordinarily difficult.

If this great similarity that I have tried to show exists between the two affections, will it not explain the wonderfully good results obtained by some practitioners in their treatment of diphtheria, and the brilliant statistics of cure which are from time to time given us?

Having raised this interesting, and, at the same time, practical point, I leave it for your discussion.

The infective nature of even the milder forms of diphtheritis has been one of the strongest and most reliable points, in its differentiation from such tonsillar affections as resemble it. But, that even this comforting diagnostic refuge is to-day denied us, the recent description, in the English journals, of an epidemic form of *communicable sore throat*, affecting the tonsils alone, will show.

Fox, whose opportunities for becoming acquainted with true diphtheria have been large, has summarized the principal facts brought out by his study of this "spreading quinsy," as it has been called. He tells us that it consists essentially of an inflammation of the tonsils, which extends more or less into the pharynx, and sometimes to the neighboring submaxillary and other cervical glands; that, although yellowish spots are sometimes seen on the tonsils from an accumulation of mucus in the follicles, *no* ash-gray, tough, leathery membrane (characteristic of true diphtheria) is *ever* seen during the course of the disease; that the individuals affected present an anæmic appearance, and that the disease is generally communicated from one to another through the medium of schools, etc. Unlike diphtheria, it is but seldom *fatal*, unless those who suffer from it have long been exposed to most unwholesome conditions. It is never followed by paralysis of sensation or motion, as diphtheria often is.

It is not accompanied by albuminuria; the pulse is full, as is noticed in cases of acute quinsy; whereas in true diphtheria it is small and feeble, indicating great prostration. It may prevail in a district where no true diphtheria is known.

The average duration of the disease is about ten days; and *finally*, it is essentially a filth disease, being always associated with some organic impurity of air or water. Overcrowding, saturation of soil around dwellings with slop-water, and employment of bad water for drinking purposes, are the most common insanitary conditions found in connection with infected houses.

The only points of difference, then, you will notice, between the "spreading quinsy," as it was first called by Clarke, and the ordinary "catarrhal tonsillitis," are that it is *communicable*, that it is *accompanied* by a certain amount of anæmia and depression, and that the *mortality* from it is probably slightly greater. Between it and "catarrhal diphtheritis" how narrow is the diagnostic line of demarcation!

I am not aware that such epidemics as are described as occurring in England, by Fox, Vacher, O'Connor, Thorne, Bird, and others, have occurred in our own country; but the possibility suggests itself to me that some of our milder epidemics of diphtheritis may, in reality, be but the disease described by them. The point is a new one, and will bear further investigation.

Who will not recognize the picture of the next affection to which I shall ask your attention? It is not a recent one; Hippocrates has described it. It is easily diagnosed: an inflamed, sensitive, discolored, swollen, and irregular tonsil; a relaxed and œdematous uvula; inflammation and tumefaction of the palatine folds, an angry-looking tumor, protruding far into the mouth and pharynx. A disease about the progress and prognosis of which there exists but little difference of opinion, the evils of acute abscess of the tonsil, be it parenchymatous or retro-tonsillar, are not restricted to uncertain appearances and to slight symptoms, nor are the sufferings and dangers immaterial.

A patient, passing his days and nights in misery, feverish, restless and apprehensive, prostrated to a degree out of all proportion to the severity of the local lesion, with intense pain and local distress, unable to open the jaws without effort, unable to swallow without fear and regurgitation; a loaded, creamy, and swollen tongue; foul breath, salivation, muffled articulation and impeded respiration; cold perspiration, pallid surface, anxious expression of countenance, and a mental depression greatly increased by want of sleep, and occasionally resulting in delirious wandering. To the practised observer, this description, incomplete as it is, will tell the tale; he will probably have arrived at his diagnosis on hearing and seeing the patient's attempts to describe his symptoms.

Is it necessary for me to allude to the differential diagnosis? Cannot diphtheritis, follicular, or phlegmonous tonsillitis, syphilis and cancer, be readily eliminated? If *not*, my picture has been but poorly drawn. Neither is it requisite, at this time and in this place, that I should enter into the pathology of tonsillar abscess further than I have done, nor dwell upon its symptomatology. *Other* and more practical questions await us. From among these I have selected the ones of predisposition, preventive and direct treatment, and finally, its dangers, for your consideration.

The best and most recent writers are in accord in assigning to the darthrous or arthritic diathesis a strong predisposing element in the production of single or recurrent attacks of quinsy. Browne tells us that there need not necessarily be, though there often is, corroborative evidence either in the family or personal history of the patient; and the fact *stands*, that the disease is most prevalent at those periods of the year and under those atmospheric conditions which are most favorable to rheumatic exacerbations. The widespread use of ginseng as a specific is probably based upon, and certainly lends color to the view. If it be *true*, an important point is gained. Recurrent attacks each year, or often at shorter intervals, indicate specially, and prominently urge, the importance of constitutional treatment, rather than simple attention to the local evil.

A strumous constitution has been advanced by certain authorities as a predisposing cause—a diathesis which renders the patient liable to inflammatory attacks similar to those frequently seen in the lymphatic glands. Browne holds, however, that this view always requires the qualifying admission that in

tonsillitis exposure to cold is an exciting cause, whereas catarrh plays no important part in the production of ordinary strumous glandular affections. As a rule, then, the affection will be found to be associated with some disordered state of health, predisposing and rendering the tonsils susceptible to cold, or due to some constitutional disturbance or diathesis. The therapeutical deduction is obvious.

I have already stated that a patient who has once suffered from quinsy is most liable to suffer again. One attack, unfortunately, purchases *no immunity*, and the question naturally arises as to what preventive treatment should be adopted. The question, I believe, can be readily answered. If there is chronic inflammation and enlargement of the tonsils, excision should be performed. In cases where the tonsil, though diseased, is too small for excision, except on occurrence of acute inflammation, amputation at that time. This proceeding may seem barbarous, but it is in reality merciful. The disease is at once cut short, abscesses that may have formed are removed or laid open, and the chance of further recurrence is almost certainly avoided. I say *almost*, for, unfortunately, we are obliged to confess to the anxious patient that recurrent attacks may, it is true, but rarely, occur in the stump of the tonsil, or in the tissues in its immediate neighborhood. As a contra-indication, it is only fair to state that Hamilton has seen the latter operation terminate fatally in a child, from an extension of the inflammation to the larynx. Such cases must, however, be exceedingly rare.

No treatment, local or general, with which I am acquainted, will with certainty prevent recurrence; but both, with avoidance of exposure, attention in matters of diet, climate and hygiene, care on the part of the patient, and the surgical means just indicated, will do much to accomplish this desirable end.

I approach the comprehensive subject of the direct treatment of the attack with considerable misgiving as to my ability to handle it within the restricted limits of this paper. So much has been written, so varied are the views, and so strenuously are they upheld as to the proper remedial means; so highly are some remedies vaunted, so deeply are others condemned; so firmly rooted are the prejudices of some, and wavering the opinions of others, as to what is best for the patient and his disease, that I can hardly attempt even a fair summary of them, and must, therefore, at the risk of laying myself open to the charge of dogmatism, record my personal views and preferences, offering them in a candid spirit for your criticism. To prove my assertion that general mistiness and vagueness exists in many quarters as to the treatment of quinsy, allow me to recall to your recollection the reports published some little time since in the *London Practitioner*, in answer to questions as to the treatment of quinsy, addressed to physicians throughout, I believe, the civilized world. My quotations will be short. To the circular letter 112 replies were received; among these was one coming from Norway, and later are eight from the United States.

The very first question, as to what drugs the person addressed generally prescribed in the disease, demonstrated that the treatment was far from uniform. The widespread belief in the efficacy of guaiacum in tonsillitis was evinced by its having the largest number of supporters—namely, 36. Next followed chlorate of potash, with 30—11 of whom prescribed it in combination with nitrate of potash, and 8 with perchloride of iron. Aconite was third on the list, with 27 supporters, two of whom gave it with

belladonna. These three, then, are proven to be the chief remedies in use, being given in 83 per cent. of the whole returns, or by 93 out of the 112 who replied.

Next, but at some distance, came saline purgatives, which found favor with 19; then saline diaphoretics, advocated by 11 practitioners. After these came quinine, used by 6, while 4 more gave it with iron. With 5 gentlemen the sulphate of magnesia, with tartarized antimony, formed the favorite measure. With others, mercury with belladonna and the sulphide of calcium, was prescribed. *Finally*, hydrochloric acid with cinchona, sulphate of magnesia with sulphate of iron, *actea racemosa*, Dover's powder, carbonate of baryta and opium, belladonna and chloride of barium, sesquicarbonate of ammonia, and last, and perhaps not least, mercury with turpentine.

Will it be improper for me to add to "this goodly array of weapons with which to battle the disease," the Chinese treatment of the affection. It renders complete the subject. The remedy is a soft stone; it is expensive, being worth twenty times its weight in silver; a dose of twenty to thirty grains of this in powder is said to be wonderfully efficacious. The story goes, that when a monkey is wounded, the animal, from natural instinct, picks out the proper medicinal herbs, masticates them, and applies them to the wound, so that successive layers are in this way laid on so as to form a mass. In time the wound heals, and the lump of dried herbs falls off. It is then picked up, found to possess peculiar virtues, and is used as above. As to its vaunted powers, I am in no more of a position to judge than of many of the remedies of which I have just spoken.

The same diversity of practice among medical men is well seen in the answers given to the question as to the resort to surgical interference. *Scarification*, to arrest the advancing tonsillitis, had 21 supporters, out of the 112, who preferred it to any other form of local treatment. With some the practice was deprecated. As to the opening of the abscess, it found 62 advocates, of whom 4 resorted to it as soon as possible; while 13 stated that they almost *never* used the knife. In no less than 17 answers, it is stated that it is *never* required, while 4 asserted that they had never seen an abscess form since they adopted the guaiacum treatment (fortunate individuals whose success is certainly to be envied!). *Finally*, curiously enough, in the eight answers received from the United States, guaiacum was never mentioned in any form; the favorite remedy was quinine.

My own view, in which I am sure many will coincide, is that an abscess of the tonsil, when its development is once assured, should be treated on exactly the same principles as an abscess in any other part of the body. It is at best doubtful whether any treatment can effectually *abort* the inception of the disease; its course can, however, be shortened. Nitrate of silver and guaiacum are perhaps the favorite abortive means which are to-day used. But is their efficacy demonstrated? The use of silver is certainly attended with one disadvantage—it produces much local discomfort; leaves a most nauseous taste in the mouth; gives rise to constant hawking and spitting, until the superficial epithelial sloughs occasioned by its application are released or removed from the inflamed membrane. With Durham, I have never seen any beneficial, or even satisfactory results, follow its use. Guaiacum may be of value, in the *very* early stages, in producing resolution. This much I am willing to admit—not from personal experience, but from the weight of authority; but when symptoms

of suppuration are manifest, it is *worse* than *useless*. Treatment, then, apart from constitutional remedies or requirements, should be based upon the principles of constant heat, moisture, and mild counter-irritation. Locally, the frequent inhalation of *steam*, medicated or not, and from any form of apparatus most convenient, just as frequently as the strength and feelings of the patient will allow; the frequent *spraying* of the throat, always grateful to the patient, with warm water alone, or slightly aromatically medicated with cologne water, and hot applications made with spicagio-piline, externally over the affected tonsil, and constantly renewed, are all measures of decided comfort and great utility.

I am not sure that *medicated* sprays (the best way of making applications) other than warm ones of glycerine, of carbolic acid (1—40—60), or salicylic acid (1 to 100), are of service. Gargles, stimulating, astringent, or indeed of any description, are not only *useless*, but irritating, as their proper use entails too much pain, and the fatigue they cause the patient far more than counterbalances any good that they do. The patient may hold warm solutions of carbolic acid, borax, etc., in water and glycerine, or even simple warm water, in the mouth from time to time, and *without efforts* at gargling, constantly bathe the tonsils by throwing the head backward. Externally, severe counter-irritation, leeching, and other depletive measures, are to be *condemned*. The disorder is one which calls much upon the strength and vital powers, and it seems to me that it behooves us to husband the forces rather than diminish them by heroic treatment.

The difficulty in swallowing being great, the less the patient is "pestered with physic, the more comfortable will be his day." A time-honored custom leads us to believe that an emetic will render efficient service early in the attack. A non-depressant should, to say the least, be selected; a saline laxative can do no harm, followed, while the fever and pulse are high, by aconite, perhaps in combination with, if the indications exist, morphine, tartar emetic, or guaiacum; as the case then progresses, stimulants and tonics are required in turn.

I shall now be asked whether I favor scarification and early surgical interference with the abscess.

Every sensible practitioner studies the feelings of his patient; every good surgeon avoids the uncertain or unnecessary use of the knife; but so marked is the suffering, if the tonsils be much swollen—so great is the relief if they be efficiently scarified—that to my mind no doubt can exist as to the propriety of the operation. It is not very painful, sometimes comparatively painless, and the relief that it affords to existing pain and tension is often immediate. Cohen holds that the facilitated circulation in the parts promotes the prompt resolution of the inflammatory process. The incisions certainly sometimes open abscesses in the interior of the tonsil, the existence of which, though conjectured, could not have otherwise been determined, and in all cases open up a path for the escape of matter without waiting for the slow process of nature.

Equally clear, I hold, is the duty of the surgeon when his finger—and I know of no occasion in the treatment of throat affections where a "tactus eruditus" is more requisite—has told him that suppuration is already evident. There can be no doubt as to the propriety of incising the abscess. The surgical principle involved holds good here as elsewhere in the body, and the abscess once incised and its contents discharged, recovery is prompt.

In either of these little operations the surgeon will remember the requisite precautions when any pointed or cutting instrument is used in the region of the tonsil. I need not dwell upon them.

In the treatment of all cases of quinsy there must be a certain amount of anxiety in view of the serious complications possible (but, fortunately, not probable), and therefore some reservation in our prognosis is necessary. Cases of death from the disease have been reported. According to the mortality returns of England and Wales, 400 persons die annually from the effects of it; but this surprisingly large percentage is probably due to errors in diagnosis, or to an association of the affection with more serious diseases, especially exanthematous conditions. Very rarely, as in young children, death might occur from inanition. Browne has seen a case of quinsy in a child of ten, but the affection rarely develops before puberty. If both tonsils are affected at one and the same time, as is occasionally seen, the case is a *serious* one, and may terminate fatally by suffocation if respiration is not relieved by excision of the glands or the performance of tracheotomy. Such an instance is reported in the *Lancet* for 1875. Porter tells of a case of this kind in which a soldier, unable to procure immediate assistance, passed a narrow tin tube between the swollen glands and kept it from slipping down his throat by a string, one end of which he tied to his teeth. Tolerating this rude apparatus for some hours, he reached a surgeon, who found it firmly grasped by the opposing tonsils. Free use of the history reduced the tumefaction, when the tube was removed and the patient recovered. I myself have been called from bed to relieve the urgent dyspnea caused by swollen tonsils blocking up the pharynx of a child, and have done so by at once excising both. Laveran gives us the details of a case which he lost through an extension of the inflammatory process to the larynx, with œdema of the glottis. In a like instance, Puech saved a patient by a tracheotomy, and others are upon record. Among the rarer complications, cases of suffocation from the sudden breaking of the abscess and discharge of its contents during sleep, into the larynx and trachea (Stokes, Littlejohn, Watson, and Wagner), ulceration into the maxillary or carotid artery, with fatal hemorrhage (Norton, Ehrmann), and, finally, paralysis of the soft palate and contiguous parts following tonsillitis (Putnam, Hardy), and death from severe cerebral disturbance, to which the autopsy gave no clew (Wagner), will all be found in the literature of the affection. Fortunately, they are altogether exceptional. It has probably been vouchsafed to but few of us, if any, to see them. The usual history of the complaint is that, directly the abscess has been opened or has broken, convalescence is perfect and speedy, the attack seldom lasting more than a week, except in those, for the patient, unfortunate cases in which numerous small and disseminated abscesses occupy the tonsil, or where one tonsil, having been affected and the attack having terminated by resolution or discharge of the abscess, the opposite gland, within a day or two, is attacked and proceeds in the whole length of suppuration. The illness may, in such instances, extend to two or even three weeks.

I now return, for one moment, to our original classification of tonsillar inflammations, to say a word in relation to peri-tonsillitis and its treatment, as well as that of follicular inflammation. The former disease is well known to us all. It is a common affection, invariably acute, and rapidly runs its course

with distinctive appearances. We see it usually in front of the tonsil; its symptomatology, which is at best but slight, and its course, are too well known to you for me to dwell upon. The practical point is, *how best to treat it.*

Nothing will give you more satisfaction, greater relief to your patient, nor more quickly cause a resolution of the inflammation in either of the two affections named—if your experience coincides with mine—than the hourly inhalation of steam as hot as can be comfortably borne, associated with the use of a gargle of chloride of zinc, some two or three grains to the ounce. I purposely omit the mention of all other local remedies. Constitutional indications are of course to be met, as I believe, from experience, in the efficacy of those proposed, and feel sure that your experience will corroborate my endorsement.

Let me digress here for one moment, to say a practical word in relation to the use of gargles. The time-honored institution is not always of use—sometimes productive of absolute harm—and in probably a majority of cases gargling is an act incompletely, and therefore uselessly, performed. Is this not excuse sufficient for bringing so apparently trivial a subject before you?

I would suggest that to use a gargle three or four times daily, as is usually prescribed, is insufficient; and to use a large quantity, and for several minutes together, is not only *unnecessary*, but often *irritating*. A gargle should be used—proper indications existing in a given case—in quantity not more than a teaspoonful at a time, and not less than one dozen times a day.

Cohen tells us that the usual method of retaining a quantity of fluid in the mouth and keeping it in motion, between the base of the tongue and palate, by repeatedly forcing an expiratory current of air through it, while the base of the tongue is elevated so as to nearly touch the palate, is not only a *painful muscular exercise* in sore throat, but is *inefficient* in bringing the fluid in contact with anything else than the *palate* and root of the *tongue*. In order to reach the pharynx, the fluid must be submitted to the action of the constrictor muscles (often an impossibility with certain people), but be released without completing the last phase of the act of deglutition; a partial act of swallowing being made, therefore, and frequently repeated—a practice which is often difficult to acquire, and which is also, as I have said, painful in sore throat. A much better and less painful procedure is to bring the fluid in contact with the inflamed parts, by letting it flow upon them by gravity, as the head is turned to one side, backward or forward, as the case may be, so as to wash the various parts or portions of the surface in succession.

With this hint I take leave of this portion of my subject.

Moderate hypertrophy of the tonsils is so common an affection among children and even adults, so well understood are its ordinary subjective symptoms, and so easy of detection its physical evidences, so unimportant its results in a certain proportion of cases, and so little do many patients complain of pain or even discomfort, that it is, perhaps, too often lightly regarded, and passed by without serious thought as to probable or possible consequences, by the general practitioner. He ascribes the functional disturbances caused by their presence to other causes, or, more commonly, discouraged by his attempts at ineffectual local or general medication, undecided as to the disputed questions of causation and pathology, he pays but little regard to their active treatment. This,

in many respects, unfortunate view, is strengthened by an idea—common among the laity—that the affection is one that will continue, at best, but a few months or years, and that the patient, if a child, will, as it is expressed, “grow to the tonsils.” With such an idea they cannot see the necessity or utility of topical remedies, and are not willing to use more than the mildest placebos. The well-read physician, on the contrary, *should* appreciate how important are the pernicious effects of hyperplastic tonsils upon the general health, in the more extreme cases. He has, in his every-day practice, ample opportunity of witnessing the evil consequences which spring from their prolonged presence; of appreciating the importance to the physical welfare; of the conditions and results to which they give rise; and *should*, therefore, lend his powerful influence in deprecating this apathy and inactivity.

I propose to do my share in this good work tonight, by calling attention specially to these unfortunate but preventable results, as met with in the more extreme, but still not unusual cases; not forgetting, however, those of less importance, as far as the sequelæ go, in order that both classes, with their therapeutical indications, may be put fairly before you for discussion—the indications then agreed upon, to notice briefly the vexed question of surgical interference.

If a case presents itself of comparatively recent standing, the hypertrophy moderate and the tumor of soft and elastic consistence, with but slight symptoms, it cannot be questioned that constitutional measures, associated with local applications, will often eventuate in partial resorption. How otherwise can we account for the fact that the affection is comparatively rare after puberty, while exceedingly common in childhood? We certainly cannot imagine that all, or even a large proportion of the children so cured, have been operated upon for the relief of the malady. And even if this desirable result of absorption be not fully attained, success in arresting the progress of the growth so often crowns persevering effort, that the task is undertaken by both parent and physician with confidence, and the slight hypertrophy which remains, being stationary, offers no reason which makes it desirable to interfere further with it. Nutritious diet, then, with careful attention to general hygienic measures, the administration of oil, vegetable and mineral tonics, in depraved conditions, with remedies calculated to promote absorption of the hypertrophied tissue, if the general health be up to the normal standard, may be prescribed with safety and taken with evident benefit. Local applications of silver, copper, iron, iodide of zinc, tincture of iodine, and the like, may be entrusted to the parent or to the nurse, and frequent compression of the gland, as recommended by Quinart, “massage of the tonsil,” may, finally, assist the process of absorption. The above cases, if well chosen, certainly present a fair chance of success by the combined treatment; but how greatly modified must this statement become when the tonsils are *old*, much *enlarged*, and thoroughly indurated; of how much more serious import are the sequelæ to which they give rise; of how much more pressing importance the question of treatment.

Yeardsley, Shaw, Robinson, and others have clearly shown us the results which spring from the presence of such tonsils. The pulaceous secretion which blocks up the diseased follicles that honeycomb the hypertrophied glands, if long retained, becomes putrescent. The *consequences* are *apparent*. The air which the little patient breathes becomes tainted in

its passage to the lungs; the patient *lives* in an impure atmosphere. And, again, "the alimentary bolus, though lubricated in its passage through the bucco-pharyngeal opening, carries with it a quantity of morbid secretion, which rapidly sets up dyspeptic trouble, and, absorbed with the circulation, leads finally to unhealthy nutrition."

If the tonsils enlarge, as they commonly do, toward the median line, the faucial opening is often most markedly reduced in size; so much so in certain instances that mechanical dyspnoea is no unimportant symptom. Shaw, in the case of a child of three years, was obliged to perform a tracheotomy to save life. In others, and when the hypertrophy is exaggerated in this direction, deglutition is a fatiguing and occasionally painful process, though this pain seems, in many cases, to depend rather upon soreness in occasional attacks of inflammation, to which such tonsils are very subject, rather than to mere alteration in shape and size of the glands themselves.

If the enlargement takes place downward, it may press upon the larynx and even prevent phonation. Such a case is reported by Thompson, and Cohen has known a tonsil to press the epiglottis down and to one side in such a manner as to prevent deglutition of solids, and give rise to suffocative attacks.

If in the upward direction, more or less obstruction of the posterior nares, and perhaps compression of the Eustachian orifices, preventing the renewal of the air in the middle ear, are but natural results, and hence the noisy and laborious oral respiration, especially during sleep, and the "throat deafness;" while, on account of the obstruction to free motion of the velum, and the mechanical obstacle to the emission of sound, the voice acquires that characteristic nasal and muffled *timbre*, almost diagnostic of the affection—the consonants l and r being specially difficult—the so-called *Parabolia literalis*.

I am prepared to admit that different opinions are entertained in respect to this "throat deafness." We certainly see constantly every conceivable variety of tonsil, both in extent and direction of enlargement, unaccompanied by deafness. Verrier, indeed, says that this very deafness can be caused by their ablation. Nor does the mechanical explanation that the enlarged tonsil blocks up the Eustachian tube seem to be always true, in fact. Holmes holds that the deafness in these cases is due rather to chronic thickening affecting the mucous membrane of the fauces near the enlarged tonsils than to the mere change in shape and size of these glands themselves; and in this view he is upheld by Hinton, Harvey, Forster, Pollock, and others.

All of the phenomena then, which I have described, may be present in adults as well as children, but several recent writers, notably Robinson, have shown us that there are *others* which relate almost solely to children—namely, "those which attach themselves naturally to arrest of development." A well-known physiological law, the latter tells us, is expressed in the following terms: Whenever an organ of the body, during its period of growth, is thrown into disuse or cut off completely from its normal function by some mechanical obstacle, *deformation* and *arrest of development*, followed by *atrophy*, are natural sequels. The application of the law follows. Owing to the passage of a less quantity of air through the nasal and oral passages in the condition under consideration, a diminished volume also enters the larynx and lungs. What is the result? The nasal passages do not increase in capacity proportionately with the

growth of the child, the alae of the nostrils sink in, and this lack of growth affects, in an equal degree, the palatine arch. The alveolar process of the upper jaw is small and the teeth crowded. Consequently the olfactive and gustatory senses are restricted.

Still further, taking into view the great flexibility of the walls of the chest in children, it may be understood how they should be subject to imperfect expansion, with resulting insufficient supply of oxygen and imperfect accomplishment of the chemical blood changes, which take place in the lungs when the air is prevented by the above causes from fully distending these organs. In the act of inspiration, two distinct operations are performed—*first*, to create a tendency for a vacuum the thorax is expanded; *next*, the weight of the atmosphere causes air to enter the lungs. By the free admission of that air into the interior, a balance is established between the pressure of the atmosphere on the outside and that on the inside of the chest. Consequently, though the parietes may be thin and pliant, their movements can be performed with perfect facility.

But quite a different state may be expected. Shaw tells us when the expansion of the chest is unaccompanied with a corresponding dilatation of the lungs, take, for example, a case of hypertrophied tonsils, or one in which the larynx is closed, so as to impede the entrance of air; it is then obvious that if the thoracic walls *could* be expanded there would be nothing to counterbalance the weight of the atmosphere without. In such cases the chest is *incapable* of being expanded, or it is expanded *imperfectly*. To the best of their ability, the intercostal and external accessory layer of respiratory muscles elevate and widen the area included within the sphere of the ribs. The diaphragm also acts on the free margin of the chest, downward and concentrically, to increase the vertical diameter, *but* the pressure of the atmosphere interferes with their effect, and the pressure from without tells mostly upon the weakest parts of the compages. These are, unquestionably, situated in the line of junction of the costal cartilages with the ends of the ribs. Accordingly it is there that the chest is principally *indented*, and this indentation leads to the sternum being abnormally protuberant—in other words, to "pectus carinatum."

If a child, then, suffer from enlargement of the tonsils, may not the encroachment of these glands, upon the calibre of the air-tube, diminish it to such a degree that the air will not only enter with difficulty, but fill the lungs incompletely? and, is it not at least supposable, in such an instance, that the long continuance of the dyspnoea thus produced will, perhaps, imperceptibly, eventually lead to the chest becoming of the "pigeon-breast" shape? Dupuytren, Coulson, and Warren, support the theory, and Shaw, Pitla, and Forster, report such cases. On the other hand, Holmes asserts that deformity of the chest is *not* connected with hypertrophy of the tonsils more frequently than the known occurrence of both pigeon-breast and enlarged tonsils in weakly children would render probable.

Be the cause what it may, we do not need competent authority to tell us that the physical development and proper growth of children, thus affected, is seriously impeded; that their nutrition languishes and their muscular energy and activity are markedly diminished—the fact is self-evident.

Shall I add to this catalogue of evils the *lesser* ones, the half-open mouth of the patient, his noisy breathing and stupid appearance, his liability from an extension of the catarrhal process to inflamma-

tions of the larynx and nares, or the *greater*, which exist in the influence, that these hypertrophied masses upon the lateral walls of the pharynx exert by their close relations and pressure upon the large nerve-trunks of the neck? May we not have from this latter cause "that perversion of nerve-force in, or that changed condition of circulation about the pneumogastric nerves," which shall produce, as a result, nightmare, restless and broken sleep, with asthmatic difficulty of breathing, as shown by Bert and Traube, and even spasmodic cough, through their morbid influence upon the muscular layer of the bronchial tubes? Porter has recently reported two such instances in which the tonsil was, beyond question, the cause. And still further, is this influence confined to this portion *alone* of the air-passages? May not either spasm or cough, produced after this manner, also affect the larynx? Does not, moreover, the same cause hold good and true in regard to these enlargements exerting more or less pressure upon the large blood-vessels of the neck, thus imposing an obstacle to the ready flow of blood to the brain, and to its circulation in that organ?

I have, within the past year, excised the greatly hypertrophied tonsils of a child, eight years old, one of whose most marked symptoms was severe and distressing sick-headaches, without appreciable constitutional cause, coming on every three to four weeks, and lasting some three days. For three years they had thus been constant, and were increasing in severity with successive attacks. The removal of the tonsils caused them to disappear at once, and for nearly a year there has been no return. Cannot a possible, but even a probable relation be traced between the two conditions?

Explain it as you may, experience teaches us that the results of such compression are diminished nervous energy and retarded physical development.

I offer these interesting points for your consideration, and call your attention to an excellent and suggestive article upon further indications for the operation by Voss.

As to the treatment of the affection, there is, it seems to me, but little room for question. On one side stands the picture that I have drawn of its possible and actual results; on the other, their immediate relief, with speedy and permanent benefit, by a safe, simple, and almost painless operation. Can there be any hesitation in our choice? Is the fact not to-day evident to the minds of all, whose studies and experience fit them to judge, that "hypertrophy of the tonsils" is only to be satisfactorily treated by the one method of *excision*? Do we need to refer to the authority of the ancient teachers to sustain our position. Even before *Ætens* excision was recommended. The operation which *Asclepiades* designated under the name *homoiotome*, cannot, we are told by *Velpeau*, be any other thing, and finally, has not *Celsus* also described it in this phrase: *Si ne sic quidem resolvuntur, humulo excipere et scopello excidere?* I shall be answered that other methods of removal have their advocates. Granted; but has experience shown us that the scarifications eulogized by *Asclepiades* and *Celsus*, and in more modern times by *Berard* and *Fabre*, the ponderous chain *écraseur* of *Chassaig-nac*, the twisted wire of *Maisonneuve*, the difficult and dangerous ligature of *Siebold*, *Physick*, *Chevalier*, and *Bell*; the more modern *galvano-cautery*; the electrolytic or hypodermic needle; the inadequate and slow action of nitrate of silver; the painful *Vienna paste*; the *London paste*, necessarily repeated again and again; caustic potash, with its attendant high in-

flammation; chromic acid, and the like, all but descendants of the actual cautery used by *Mesué*, have given us practical or desirable results?

Nothing short of an actual slough can do good, if caustics are used, and no stimulating and incomplete application can offer much hope of acting upon such a structure. *E. Wagner* candidly states, that after patient, persistent, and regular applications, continued through months, he has never seen a true diminution in size, at most superficial ulcers.

Why, then, waste time, or inflict pain, by having recourse to useless local measures?

It is by no means requisite to remove the *whole* of the hypertrophied mass with the guillotine or tonsil bistoury, but the greater part certainly should be. *Hamilton* pertinently remarks, that if no good reason can be assigned why the gland *should not* be removed more fairly than is generally recommended, a sufficient reason can be assigned why it *ought to be*. When the whole or two-thirds of the gland is cut away, no more trouble is experienced from this source, but when one-half or one-third is removed, the balance does not generally disappear, and not infrequently it again enlarges. This remark does not agree with the experience of some surgeons who have written upon the subject, and who, believing that if one-third or one-half is cut away the remainder will soon disappear, do not think it necessary to remove more than half at any time. The best rule is to remove all of the tumor that projects beyond the anterior palatine fold, and for a little distance below that point. Its cells are thus well laid open, and what with their becoming emptied, the relief occasioned by the incision through parts chronically inflamed, and the subsequent contraction of the cut surface, by cicatrization, the portion that is left shrinks somewhat, and sinks into the side of the fauces, to give no further trouble to the patient. It is a mistake, however, as has already been alluded to, to count upon *too much* shrinkage. Cases have come under my notice more than once, where, the section made, the patient was told that the tonsil would *now* grow small by a process of cicatrization. *Too often* does the surgeon "lay this flattering unction to his soul," to compensate for an incompletely and unskilfully performed operation. The guillotine—but an improvement upon the old *kiotome* of *Desault*, made upon the English pattern—will, I believe, answer the best purpose, in the largest number of cases. The double vulcellum and tonsil-histoury may be rendered necessary by the peculiar configuration or location of the tonsil, or be preferred by some who follow the precepts of our forefathers—*Blandin*, *Amussat*, *Baudens*, and *Velpeau*—in the case of adults. The details of the method of using either I do not enter into, further than to say, or rather suggest, that in using the knife it is better, as recommended by *Louis*, but for other reasons, and *contrary* to the advice generally given, to cut from below upward; the large vessels enter the tonsil in its upper part, and are thus cut through last, while the knife passes away from, and not into, the collection of blood, which forms below in the mouth as the section is being made, and avoids wounding the tongue.

Hemorrhage—that *bête noir* of many practitioners—is usually inconsiderable, and soon ceases spontaneously. *Hamilton*, out of fifty-two operations, had an alarming hemorrhage in three only; *Voss*, who has had an experience of 347 cases, speaks lightly of its dangers, and *Guersant*, in more than one thousand children, reckons no more than three cases out of this

number in whom formidable bleeding occurred. If considerable, it is probably due to the careless injury of the tongue or lips, or of the palatine folds, during the operation. This is a common cause and should be borne in mind. Again, by a too deep incision, the rich venous plexus, which lies at the bottom of the tonsillar fossa, may be opened into, as shown by Panas. Cohen holds that hemorrhage is more likely to follow the use of the guillotine, rather than that of the bistoury. My experience has been just the contrary.

Hemorrhage, to an alarming extent, may certainly occur. I, myself, have treated three such cases, and others are upon record where the carotid has been opened, and it has proved fatal—as Tënon, Portal, Burns, Bécéard, and Barclay state that they have seen. The careful surgeon will, therefore, be always prepared for the unknown and, perhaps, abnormal distribution of the vascular supply, or for the special diathesis, which gives rise to bleeding.

How often is the physician—be he family practitioner or specialist—asked the question, Will not the patient always have a tender throat, one susceptible to cold and inflammation; one liable to diphtheria? or will the voice not suffer after the removal of the tonsils? And how satisfactory it is to be able to give a most emphatic answer in the negative; to assure the anxious inquirer that, in suitable cases, *nothing* but good can come of the operation.

If I have succeeded in convincing any wavering minds of this fact, or in strengthening the views of others upon this point, my *task is done*. In its execution, I am fully conscious of many sins of both omission and commission. Very much more might be said, for I have treated but a small part of "the thousand ills that flesh is heir to." The suggestions that I have made are tendered with a feeling of good will, and desire to aid in our common work. Would that they were more worthy of your acceptance.

NEGATIVE PRESSURE.

By G. M. GARLAND, M.D.,

PROFESSOR OF THORACIC DISEASES, MEDICAL DEPARTMENT, UNIVERSITY OF VERMONT.

According to Webster, "science is literally knowledge, but more usually denotes a systematic and orderly arrangement of knowledge," and that anything may be *scientific*, it must agree with the rules or principles of science. All expressions, therefore, which are used by recognized authorities, and which contribute to a systematic and orderly arrangement of knowledge, are termed scientific. Among such expressions is the one which heads this article.

Negative Pressure is a term which one encounters constantly in German and French medical books. Among American and English writers it has met with less favor, and has, indeed, at times been exposed to public gaze as an object of ridicule by those who have failed to comprehend its meaning. At first glance, one might be misled to the inference that the term in question denotes a pressure less than zero in amount. Since we are unable, with the mechanical agencies at our command, to produce a complete vacuum, and since it is impossible to conceive of a pressure less than vacuum, it might be deemed absurd to invent a term for that which has no existence, and which can enter into no problem of mechanics. When, however, those who have endeavored to vilify negative pressure, and have de-

nounced its claims to a scientific character, once understand its correct usage, they will discover that they have been demolishing phantoms of their own imagination.

On referring to standard works on physics, we are taught that a force is defined by three factors, viz.: 1. The place or part of body to which it is applied; 2. The direction of its action; 3. Its magnitude. Each of these factors is independent of the others, and is treated by terms appropriate to itself. Now, the direction in which a force acts is that of the motion which it tends to produce, and Ganot* says: "When we are considering several forces acting along the same line, we may indicate their direction by the positive and negative signs." This use of the terms positive and negative is universal in treatises on physics, and it will be immediately obvious, from Ganot's definition of their meaning, that they do not refer in any way to the magnitude of any force. They are simply algebraic expressions to indicate, in a concise, systematic, and orderly manner, the direction in which one force is acting as contrasted with that of some other and opposing force.

Now, pressure is simply one manifestation of force, and therefore we should naturally expect to find the direction of its application expressed in the same formulae as in the case cited above. That pressure is thus expressed in physics may be learned from the following definition. In speaking of stress, Rankine† says that it is a general term to comprehend various forces which are exerted between contiguous bodies, or parts of bodies, and it is divided into three classes, of which the two following interest us at present:

"1. Thrust, or pressure, is the force which acts between two contiguous bodies, or parts of a body, when each pushes the other from itself.

"2. Pull, or tension, is the force which acts between two contiguous bodies, or parts of a body, when each draws the other toward itself. . . . In expressing a Thrust and a Pull in parallel direction algebraically, if one is treated as positive, the other must be treated as negative. The choice of the positive or negative sign for either is a matter of convenience. The word '*pressure*,' although, strictly speaking, equivalent to '*thrust*,' is sometimes applied to stress in general; and when this is the case, it is to be understood that thrust is treated as positive."

Once more I emphasize the fact, therefore, that the terms positive and negative, as here used, have no reference to the amount or magnitude of any pressure, but simply indicate the direction of application.

In comparing two forces which are acting in antagonism to each other, Rankine says that thrust is always treated as positive. When, therefore, one of the forces under consideration is the pressure of the atmosphere, as is the case in the various manifestations of the phenomenon of suction, this atmospheric pressure is always designated by the positive sign, because it is always exerted in the direction of thrust. All the other forces, which in a given case are acting in an opposite direction to that of the atmosphere, are considered negative, and the pressure which they exert upon any body, or parts of a body, exposed to their action, is termed Negative Pressure.

In the *Medical Record* for September 27th, Dr. R. Van Santvoord, of New York, published a criticism upon Negative Pressure in which he shows that he has failed to understand the proper meaning of the

* Ganot. *Elementary Treatise on Physics*, sixth edition, p. 13.

† Rankine and Bamber. *A Mechanical Text Book*, p. 115.

term. He says: "The idea of negative force is absurd. Force is essentially positive." I allow that it would seem absurd, as I have previously said, to speak of a force less in amount than vacuum, but I hardly think that Dr. S. is prepared to denounce all works on physics as absurd because they treat force as positive or negative according to the direction of its action. I am somewhat surprised that Dr. S. allowed himself to be so misled regarding the meaning of the term in question, because, in my introduction to "Pneumono-Dynamics," to which he refers, I declare emphatically that the term Negative Pressure "does not imply anything as to the magnitude or intensity of any force, but simply designates the manner in which that force is applied."

Again Dr. S. says: "To speak of negative pressure instead of atmospheric pressure is exactly equivalent to speaking of the rising of the sun when we mean the rotation of the earth." As every one knows, "the active agent in 'suction' is the pressure of the atmosphere outside of a more or less complete vacuum." This definition of suction is very true as far as it goes, but it is unfortunately incomplete in that it ignores other agents equally important with the atmosphere in the phenomenon of suction. When two bodies lie in contact with each other, the atmospheric pressure undoubtedly tends to retain them in that position. No manifestation of suction is possible, however, until an attempt is made to separate these bodies by forces which are antagonistic, or negative, to the atmosphere. Hence, if the atmosphere about a vacuum is *one* active agent in suction, the forces, chemical or mechanical, which create the vacuum are none the less essential. The atmospheric pressure drives up the column of water after the ascending piston, but it is the negative force, generated by the engine outside, which lifts the piston and thereby produces a negative pressure on the surface of the water below the same. In answer to Dr. S., therefore, I fail to see why we should not speak of negative pressure, or why we should speak of atmospheric pressure, when our object is to particularize the influence exerted by those forces which oppose the atmosphere. We can hardly expect to arrive at the satisfactory solution of any problem if we ignore a portion of the factors essential to the same, or if we deprive them of terms appropriate to their clear and orderly expression.

From what has preceded, the working of negative pressure in the function of respiration will be readily understood. With the first breath of life the lungs are placed in a condition of permanent expansion. They are held in apposition to the chest-wall by the internal atmospheric pressure. By virtue of their retractility they are constantly striving to collapse, and are therefore exerting a force in a direction opposite to that of the atmosphere within. Consequently in all German works on thoracic physics, this retractile force of the lungs is called negative, and it is said to exert a negative pressure upon the inner surface of the costal pleura. In a similar manner, during inspiration, the lifting force of the chest-wall is negative to the external atmosphere and exerts a negative pressure upon the lung.

Dr. S. concludes his criticism by the remark: "To call such a phrase 'scientific' is a singularly flagrant abuse of terms."

I have shown that the term Negative Pressure is recognized and employed by authorities on physics, and that it contributes to a systematic and orderly arrangement of knowledge, and these, according to Webster, are the requisites of a scientific term.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES IN TREATMENT.

LEAD-POISONING—GENERAL PARALYSIS—FACIAL PARALYSIS.

The following case possesses a few points of interest relating to symptomatology:

A male patient, *æt.* 40, who had been in the habit of drinking a glass of cider drawn from the pipe *early* in the morning, began, in June last, to feel a "weakness coming over his entire system." His occupation was that of a waiter, and he found it difficult to perform his labor. His appetite became poor, he began to lose flesh, he vomited occasionally, he had pains in the bowels, and his bowels became habitually costive. He improved somewhat, returned to his work in July, but in August he was compelled to give up his work entirely because "of a general weakness which was all over me" (*him.*) When admitted to the hospital he was unable to extend either little finger. He had a well-marked blue line along the margin of the gums. He now has general paralysis, most marked in the arms, which are almost useless, hanging from the shoulders like flails. He has some difficulty in closing his eyes firmly, is unable to wrinkle his brow only to a very limited extent, there is slight fibrillary contractions of the tongue, and a general appearance which indicates paresis of the muscles of the face.

This was the interesting point in the case, for it was undoubtedly one of lead paralysis, and yet, in most text-books, it has been said that one of the characteristic features of the general paralysis produced by lead is that it does *not* affect the facial muscles.

The deltoid muscles were markedly atrophied; the biceps and the triceps were tolerably well preserved. Fibrillary contractions were well-marked in the muscles of the forearm. Phonation and thoracic respiration were also somewhat affected. The muscles of the arm and forearm and hand did not react to the faradic current; but when the galvanic current was applied, *slowly interrupted*, with positive pole over the brachial plexus and the negative pole on the muscles, contractions could be produced. When the positive pole was placed on the muscles, and the negative over the nerve, no reaction took place. Galvanism, therefore, was used to stimulate those muscles which the patient was unable to move, and iodide of potassium was given internally.

A second case of lead-poisoning was seen in which *delirium* was a marked symptom. The blue line was well developed, and the general paralysis was marked. It was supposed that the lead was introduced into the system by drinking ale.

EXOPHTHALMIC GOITRE—GALVANISM—NOTABLE IMPROVEMENT.

A young woman who had exophthalmic goitre, had been under treatment by means of iodide of iron pills, iodide of potassium in syrup of wild-cherry bark, and galvanism. The goitre had diminished considerably in size, and the pulse had been reduced to 74.

DISPLACED HEART SIMULATING ANEURISM.

A note was made of this case chiefly with reference to a physical sign. A female patient, on inspection of the chest, exhibited a distinct circumscribed pulsation on a level with the second rib on the left side, and about two inches and a half from the edge of the sternum. The region around the pulsation was flat on percussion. Aneurism was a snap diagnosis. But on examination it was found that the left side of the chest was, by measurement, two inches smaller than the right; there was flatness on percussion over the entire left chest; bronchial respiration; voice-sounds and vocal fremitus.

The diagnosis was fibrous induration of the lung, with dilatation of bronchial tubes gradually taking place and drawing the heart upward, and producing pleural and pericardial adhesions, so that an impulse was visible at the base as well as at the apex of the organ. The apex was beating in the fourth intercostal space.

ACUTE ARTICULAR RHEUMATISM—ENDOCARDITIS—INABILITY TO RECEIVE SALICYLIC ACID—NON-ALKALINITY OF THE URINE, ALTHOUGH ALKALIES WERE ADMINISTERED FREELY.

A young woman was the subject of acute articular rheumatism, and her case presented certain points sufficiently interesting to be worthy of mention. The local symptoms of the articular affection were prominent, a large number of joints being affected, and then an especially distinct intra-ventricular murmur indicating endocarditis.

The urine had not been made alkaline, although the patient had taken alkalies very freely. Such cases occur occasionally. She was unable to continue the use of salicylic acid because of the unpleasant feelings which it produced in her head—headache and buzzing in the ears. When those symptoms first developed, the acid was stopped and they soon disappeared. The acid was renewed, and the same symptoms returned. The acid was again stopped and the symptoms again disappeared, and that was repeated three times with the same results, when the acid was discontinued entirely. There seemed to be no question that, in this case, salicylic acid was not well borne by the patient.

The patient was nearly convalescent.

ACUTE ARTICULAR RHEUMATISM—PREGNANCY—MISCARRIAGE—ENDOCARDITIS—HIGH TEMPERATURE—RECOVERY.

In connection with the above, mention was made of a case which possessed great interest because of the unusual factors it contained.

A young lady, who had never had articular rheumatism, was seized with the affection in the seventh month of pregnancy. Her temperature rose to 109 F. in the axilla. Premature labor took place, and she was safely and rapidly delivered. Unmistakable evidence of endocarditis also developed.

The treatment for the rheumatism was alkaline—alkalies being used freely until the urine was made alkaline.

For the extreme elevation of temperature, quinine in large doses was given, which was borne very well. Notwithstanding her recent labor, the entire surface of her body was also sponged for a great part of the time with cold water, the cold being used persistently and fully, and by the assistance of those two measures, quinine and cold water, the temperature was

reduced, and, perhaps, were the chief means of saving the patient's life.

GOUT NON-HEREDITARY.

A male patient, *æt.* 36, was suffering from his *third* attack of gout, affecting the great toe joint, occurring at intervals of *four* years, and all the attacks beginning suddenly in the night. No trace of hereditary tendency to the disease could be obtained. He had been accustomed to drink a quart of beer daily for twelve years.

SINGULAR AFFECTION OF THE PENIS.

The phenomena observed in two patients were the following: Short, involuntary jerks of the penis backward, in one case accompanied with excruciating pain; in the other not, until finally in one case the organ was so retracted that it appeared as a mere nub just at the arch of the pubis; in the other case the retraction was not so marked, but the jerking gave the patient great discomfort, although it was not positively painful. In the painful case the repetition of the attacks seemed to have a certain degree of periodicity. It never was, at any one time, a week from the first manifestation of the peculiar phenomenon before the attack was renewed, and would continue for days. The longest interval of rest was five days, and sometimes the patient had one or two terrific attacks daily. In that case, also, there was no assignable cause, except a contracted meatus urinarius. Suspecting that it might depend upon that cause—that it belonged to the neuroses assignable to that condition of the male urethra, the meatus was enlarged by incision to a size corresponding to the remaining portion of the urethral canal, but without effect. A second operation was performed, very free incision was made, and the trouble entirely disappeared.

In the second case, however, there was no pain, the meatus had a full size, admitting 31, and, so far as examination showed, there was no notable abnormal condition of the urethra, except a tenderness in the region of the seminal ducts, and for that he had been injected with a twenty-grain solution of nitrate of silver, five drops being applied by means of an instrument made for the purpose, as near as possible to the portion of the urethral canal into which the ducts empty. He had seminal emissions, and for those, in addition to the local application, he was taking

R. Ext. fld. ergot..... ʒ ss.
Potass. bromid..... gr. xx.
M.

three times a day.

Both the spermatorrhœa and the peculiar phenomenon relating to the whole penis were improving. In the second case, there was an irritated condition of the rectum, which, it was thought, might have some bearing upon the difficulty relating to the penis.

ACUTE CIRCUMSCRIBED PYO-THORAX—PNEUMO-THORAX.

A patient was seen who gave a history almost identical with one already reported. [See *MEDICAL RECORD*, November 22d.] It was interesting from the fact that it was a case of acute empyema occurring in a patient who, apparently, was in good health at the beginning of the disease.

A female patient, *æt.* 39, a laundress, was admitted to the hospital November 13th, and said that she was never ill until three weeks previously; never had a cough, was able to work, etc. She suddenly became

ill in the night, had a chilly feeling, which was succeeded by fever, cough, pain in the left side, and vomiting. The next day she observed that blood was mixed with her sputa. Since that time she had not been able to work, although she had been able to be about her room, but suffered from pain in the side, shortness of breath, and her cough had continued. When admitted, there was evidence, from physical examination, of fluid in the left pleural cavity. An exploratory puncture was made with a needle, but no fluid was obtained. The breath was remarkably fetid; the sputa was muco-purulent, and, upon microscopical examination, was found to contain fibres of elastic connective tissue. This was an interesting fact—namely, the presence of elastic fibres in the sputa so early after the beginning of an acute pulmonary disease occurring in a healthy person. The urine contained no albumen. Since admission her temperature had continued elevated, and she had had two well-marked rigors. Breath constantly fetid. The hypodermic needle was introduced at intervals, but no fluid was obtained from the pleural cavity until the morning of the 25th of November, when a small quantity of pus was obtained that was extremely fetid.

December 2d.—The temperature continues elevated, and the patient has hectic. Breath offensive.

December 3d.—Physical signs still point to the presence of fluid in the left pleural cavity.

December 4th.—The visiting physician thought that a localized pneumo-thorax had been added to the pyo-thorax. It was supposed that perforation of the lung had occurred, but being unable to obtain much pus by aspiration, it was deemed best to wait for further developments.

Physical examination revealed a circumscribed area of flatness on percussion over the lower portion of the left side of the chest posteriorly, and at places within that area there were bronchial respiration and feeble broncophony, and over other parts increased vocal resonance. These signs were regarded as evidence of solidification of lung around the circumscribed empyema.

The succussion sound could not be obtained, nor was there evidence, by percussion, of the presence of air in the pleural cavity; and yet, from the history of the case and the present symptoms relating to the expectoration, it was inferred that perforation of the lung had occurred. [The case mentioned in the former report alluded to was improving, the pulmonary symptoms having, in a great measure, disappeared.]

Pathological condition which gave rise to the symptoms.

—The visiting physician gave what seemed to him to be the most probable explanation of the case, and it was, that it began as a small circumscribed pulmonary gangrene, situated near the surface of the lung, which excited a certain amount of pleuritic inflammation and adhesions before much escape of gangrenous matter took place. The chest had not been occupied by general empyema; hence the circumscribed empyema was not a sequel of that condition. It was presumed that the pleurisy was caused by the escape of decomposing lung-tissue, which produced an inflammation suppurative in character.

Indications for treatment.—The patient was not suffering from accumulation of pus in the pleural cavity, most of it being gotten rid of by expectoration. It was recommended to support the system by the use of tonics, good food, and a certain amount of alcohol in the form of wine or malt liquors. There was no indication for free incision through the chest-wall.

Progress of Medical Science.

NOTES ON THE POST-MORTEM EXAMINATION OF A CASE OF ATHETOSIS.—This is the title of a paper by Prof. Sydney Ringer, published in the *Practitioner* for September, 1879. The patient, when twenty-eight years of age, was struck down with right-sided hemiplegia, hemianæsthesia, and unilateral sweating. He subsequently recovered the lost power and sensation on the right side, but the unilateral sweating persisted. As he regained his power, the athetosis developed itself. He died of heart-disease in June, 1878. At the autopsy the brain was examined with great thoroughness. No trace of an occluded vessel could be discovered. Transverse, horizontal sections of the brain were made, but nothing was found abnormal until the lateral ventricles were laid bare, when the posterior part of the left corpus striatum was seen to be depressed and hollowed out; the membrane covering it was thickened. The left optic thalamus was decidedly smaller and flatter than the right. The soft commissure of the third ventricle was gone. Transverse vertical sections were then made through the rest of the brain, and they revealed a cyst one and a half centimetres in width and three centimetres in length, with its long axis in the antero-posterior direction. The cyst lay anteriorly in the corpus striatum—being situated in the posterior half of the lenticular nucleus, just without the inner capsule; behind it lay, outside and rather below the anterior, two-thirds of the optic thalamus; but the posterior portion of the whole left corpus was softened, and the thalamus was washed. The parts posterior to the cyst, and the spinal cord and nerves, presented nothing abnormal. The microscopical examination showed that the whole of the corpus striatum was much damaged, both the intra- and extra-ventricular portions (caudate and lenticular nuclei). Besides much atrophy and slight degeneration of the intra-ventricular portion, about one-fifth of the lenticular ganglion was destroyed, and was occupied by the anterior portion of the cyst. A few of the motor fibres (inner capsule) passing between the caudate and lenticular nuclei, and a greater number of the sensory fibres (outer capsule) passing from the filament, were destroyed. The corpus striatum was the part which suffered most, but the left optic thalamus was also washed, and a small portion of the lower and outer portion of this body was completely destroyed, whilst a considerable portion of the white matter external to the thalamus (sensory fibres of the outer capsule passing from the filament) was destroyed, and the part occupied by the posterior part of the cyst. Dr. Ringer attributes the athetosis in this case, not to the cavity, but to the damaged tissues in its neighborhood, whether in the optic thalamus, or the corpus striatum, or both. An interesting point in the case is the complete recovery from paralysis, both of motion and sensation—although a large hole remained in the most important part of the brain, and the tissues around it continued considerably damaged.

DIPHTHERIA.—Dr. W. Scott Marshall, of Centralia, Ill., is of the opinion that tracheotomy performed early in cases of diphtheritic laryngitis is of great service. He writes that he has never seen a case recover in which the voice was reduced to a whisper. His experience in this respect is not unique.

New York, December, 27 1879.

THE UNITED STATES MARINE HOSPITAL SERVICE.

THE annual report of the Surgeon-General of the U. S. Marine Hospital Service has recently appeared, and with it the Secretary of the Treasury issues a new Code of Regulations for the control of this bureau. The two documents call attention to a medical organization whose rapid growth and promising future are likely to attract some interest from the profession.

The Marine Hospital Service, organized in 1798, was for many years only an unimportant bureau in the Treasury Department, under the care of clerks alone. With the twenty cents a month assessed from seamen, and with annual appropriations from Congress, it furnished medical relief to sick seamen, but, as a rule, in an extravagant and inefficient manner. Its work as a service had no professional status or scientific value. In 1871, under the direction of Dr. Billings, Dr. Woodworth, Dr. Stewart, and others, it was reorganized and put under the control of medical men. Since then it has been steadily improving in the efficiency of its work and the character of its officers, until now, if we may judge from the figures presented, it bids fair to outrank in some respects the other government services. The two facts pointing to this are: the steady increase in the number of patients treated and medical officers appointed, and the very large number of seamen, amounting to not less than 150,000, who come under the medical care of the service. With this field, which is constantly enlarging, for the medical officers to work in, the profession may expect of them some contributions of value to medical and surgical science.

The statistics given in the Surgeon-General's last report show that 20,922 patients were treated in the year ending June 30, 1879. Only about 15,000 were treated in 1877. The number of medical men in the service is between thirty-five and forty, not including

seventeen acting assistant surgeons. These officers are appointed after a severe competitive examination, seventy-eight per cent. of the applicants having in the past year been rejected. This per cent. is somewhat smaller than that of the army, which was in 1878-9 about eighty-six per cent. But it is large enough to show that merit is essential to an appointment in the service. The positions held by the medical officers are those of assistant surgeon, passed assistant, and surgeon. Promotions are made after a certain length of service, and after passing examinations. The pay is, we believe, about the same as that of the army and navy, but, from the character of the service, advancement is more rapid.

The professional work done by this service must necessarily be of a peculiar and somewhat limited character. One-fifth of the patients suffer from chancre and syphilis, while there is an equal per cent. of malarial diseases and a somewhat smaller proportion of rheumatic cases. Attention to the hygienic surroundings of seamen is naturally a matter of concern, and this as well as questions of quarantine have already engaged the attention of the Surgeon-General. In June last an order was issued directing the medical officers of the service, when called on to do so, to make physical examinations of seamen about to ship. A considerable number of examinations have been made, with the result of finding from five to ten per cent. of those proposing to ship, physically unfit to do so. This has fully justified the undertaking, and it will, as it grows, undoubtedly secure an immense benefit to the seamen and the shipping interests, as well as furnish valuable scientific data.

The work of the Marine Hospital Service has so far been more practical than scientific—not many of its contributions to medical literature having yet, in the latter respect, reached a high standard. Its adoption of the metric system, however, gave a great impetus towards a rational method of measurement, and there have been papers upon venereal diseases, and yellow fever and sanitation, of considerable value. Matters of public health and quarantine have now been relegated to the National Board of Health, but in the history of public, and especially national sanitation, the work of the late Surgeon-General Woodworth will have a prominent place. It will be expected that the question of how to check venereal disease and how to regulate prostitution should receive attention and help from officers who deal with a class that suffers more than any other from its ravages. Such attention has to some extent been given.

It is in these two directions of public sanitation and of the management of venereal disease that the Marine Hospital Service has so far been especially prominent. But it will be strange if, with the field it has before it, and with what is, for statistical purposes, one immense hospital treating 20,000 cases a

year, a wider and higher range is not given to its usefulness.

The publication of a revised code of regulations indicates a stage of more perfect organization and discipline. The general tenor of those regulations is, we believe, somewhat similar to that of the army. They aim to secure stricter discipline and more efficient methods for conducting the work of the service. While they will undoubtedly do this, they appear to be exceedingly elaborate and minute; and, if any criticism were made, it would be that they attempted to pin things down almost too closely. Thus, we can admire the moral elevation which inspired paragraph 93, forbidding all profane swearing among officers and employees; but it has generally happened that attempts to enforce this portion of the decalogue by statute have had in them more of beneficent intention than practical effect.

A new feature is a provision for boards of inquiry and discipline. Before these, delinquents will be brought, tried, and, if necessary, disciplined.

The medical officers have heretofore been embarrassed and hampered in their medical work by the great amount of clerical work which fell upon them. Much of this, it is stated, will be removed under the new regulations.

Under their workings, therefore, which are likely to prove, in general, excellent, with an increasing number of officers, hospitals, and patients, the future work of the Marine Hospital Service will be watched with much interest.

THE LUNACY REFORM MEETING.

THE public meeting of citizens to discuss the subject of lunacy reform was held on Dec. 18th, as announced, and was very successful in every way. Speeches were made by Mr. Geo. W. Curtis, Dr. Belkows, Dr. Storrs, and Dr. E. C. Seguin; letters were read from Dr. Willard Parker, Mr. Sewall, and Mr. Frank B. Sanborn and Hon. Dorman B. Eaton. Full reports of these have appeared in the daily press, and we need not go into any details about them now.

The speeches were, in their general character, entirely devoid of personality or inflammatory appeals; but were, nevertheless, extremely earnest and determined in calling for reform. It was shown very clearly that our asylum system is imperfect and behind that of other countries; it was shown, further, that the care of the insane is a branch of public service that, above all others, needs to be kept constantly before the public eye; and it was shown that the State and city are expending immense and continually increasing sums on the insane, without having yet secured adequate provision for them. These facts, without taking into account the more special evils, were found sufficient reason to urge the formation of a Board of Lunacy Commissioners; and the

securing such a board was made the particular object of the meeting. At its conclusion, resolutions were adopted recommending to the Legislature the establishment of such a board, and appointing a committee to frame a bill covering that end.

The same committee was authorized to set on foot the organization of a National Association for the Protection of the Insane. Such an association will undoubtedly be of great service, as furnishing a nucleus for further effort, and giving an assurance that the work of reform is not spasmodic, but is placed on a broad and permanent basis.

Much wisdom was shown in the concentration of the efforts of those wishing lunacy reform upon a single object—that of securing a lunacy commission. Such a board we have before advocated as being an essential in reform, and it now appears to be the first and wisest step that can be taken in that direction.

With an efficient Board of Lunacy Commissioners, raised above political influences, and furnished with proper authority, every improvement possible in asylum management can be expected to be brought about in good time.

The tone and management of the meeting showed that wisdom had been gained from the wretched experience of last winter. No petty and personal charges were made, but the demand for reform and for a lunacy board to initiate and perpetuate it was based on the unassailable ground of the helplessness of the insane, the rights of the citizen, and the success of lunacy boards elsewhere.

It is to be hoped that the work begun by this meeting will not be dropped. If placed in energetic and fearless hands, with the impetus public spirit has now given it, we may expect before long to find the care of our insane becoming less of a reproach to medical science, and of an offence to humanity.

THE VENTILATION OF CHURCHES AND THE SPREAD OF CONTAGIOUS DISEASES.

In a recent number of the *New York Freeman's Journal*, its editor publishes an address on State Medicine, delivered by Dr. O'Sullivan before the Medico-legal Society, and comments editorially on those portions referring to church ventilation and the spread of contagious diseases. It is somewhat surprising that the only excuse he offers for the bad ventilation of the Catholic churches is, that there is danger of exposing such worshippers as remain to the draughts from open windows. In order to make the necessary change of air, it is requisite that the churches should be empty at the times referred to between masses. A few moments would be all that is required, while those in waiting could assemble in some adjoining room. It is true that this would involve the expenditure of some time and some extra trouble to the sextons, but in a fresher atmosphere the good people could doubtless pray better. The plan is so simple that many of

the priests of the leading churches are inclined to adopt it.

We speak of the Catholic churches in this connection, because none of the other religious edifices have their audience-rooms occupied by large numbers of people for so many hours at a time.

In the matter of spreading contagion in churches by the attendance of persons who are nursing cases of infectious diseases, our learned friend ventures the opinion that such persons are no more dangerous than physicians. The cases of the nurse and physician are hardly parallel ones in such a connection. The nurse is in constant attendance upon the sick one, is saturated more or less with poisonous emanations, and uses no precautions against the spread of the disease. Such persons, too, are apt to attend mass when the largest numbers are present, in the earlier parts of the day, and when the air is already loaded with impurities. The physician, on the contrary, knowing the dangers of disseminating infection, adopts the precautions which the circumstances make necessary. He does not go directly from the bedside of the sick into a crowded assembly; he stays but a short time by the patient, has the advantage of fresh air as a constant disinfectant, and even changes his clothing when it is necessary. As a matter of fact, considering the chances to the contrary, physicians rarely carry disease, while it is a notorious fact that ordinary nurses and other attendants upon the sick are most active disseminators of poison.

The distinguished editor of the *Freeman* advises that there be a little more trust in God, as the safeguard against the dangers of which we speak; but we still believe that there is no harm in "keeping the powder dry" also.

Reports of Societies.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 4, 1879.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

The Academy was called to order at 7.45 p. m., and the minutes of the last stated meeting were read by the Secretary, DR. H. T. HANKS.

The annual report of the Treasurer was read, and showed a balance in the treasury of \$312.03.

The report of the Board of Trustees was read by DR. S. S. PIERCE, and showed a balance of \$293.97 in favor of the Academy, and a total valuation of all the property belonging to the Academy of \$81,400.

The annual report of the Recording Secretary was read, and showed an increase of 33 in the resident fellowship during the past year.

The report of the Corresponding Secretary was read by DR. JOHN G. ADAMS, and a resumption of

the publication of the volume of Transactions was recommended.

The Committee on Library reported, through the Librarian, DR. LAURENCE JOHNSON, recommending a circulating department of the library and an additional reading-room. The recommendations had been adopted by the council. The number of medical journals to be found in the library the coming year is 122. Of that number there are 24 German, 24 French, 12 English, 4 Spanish, 4 Italian, 1 Cuban, and 53 American.

The reading of the annual reports of other committees was dispensed with, and the Academy proceeded to the nomination of officers, after which a paper on

SOME OF THE COMMONER AFFECTIONS OF THE TONSILS, FROM A DIAGNOSTIC AND THERAPEUTIC STANDPOINT,

was read by DR. GEORGE M. LEFFERTS. (Vid. page 601.)

The paper being before the Academy for discussion.

DR. J. H. DOUGLAS referred to one point not mentioned by Dr. Lefferts, and which he thought of considerable importance in studying affections of the tonsils—namely, the situation of the tonsil between the arches of the palate, anterior and posterior, which in the acute stage of inflammation strangulated the gland to a greater or less degree, thus tending to keep it filled with blood, perpetuate the pain, and prolong the disease.

In chronic enlargement of the tonsils the anatomical arrangement and the effect were the same, and in most cases the strangulation was very marked, which was kept up by the catarrhal inflammation.

The practical point was to relieve the catarrhal inflammation in the acute cases, especially affecting the posterior half of the posterior arch and nasal fossa, and that could be done best by injecting those parts forcibly by means of a syringe with a long, curved nozzle, so as to remove the masses of thick mucus which had lodged there. When that was done from four to six times daily, the tumefaction of the tonsil usually at once subsided, the patient was relieved, and was able to fall asleep readily.

In chronic tonsillitis he resorted to the same plan of treatment, together with washing out the crypts of the tonsils with water and keeping them free from accumulations of secretion. When that was done, it was remarkable with what celerity the hypertrophy would disappear, and the treatment followed up from time to time had reduced the largest tonsil he had seen. He did not approve of the use of nitrate of silver, and he now rarely used a knife. With regard to hemorrhage following excision of the tonsils, he thought there would be no difficulty if the coagulum was kept thoroughly removed. He agreed with Dr. Lefferts upon the point that quinsy sore-throat occurred for the most part in those who had an arthritic constitution.

DR. BEVERLEY ROBINSON directed attention to one practical point in the differentiation of follicular tonsillitis from diphtheria. Both were contagions; but he believed that when the membrane fell off in follicular tonsillitis, it *did not reappear*, as was the case in diphtheria, two or three days after falling of the membrane. Albumen also was present in the urine of the diphtheritic patient, while in cases of follicular tonsillitis it was absent.

He agreed with Dr. Lefferts regarding the inefficiency of gargles, the benefits from inhalation, the uses of scarifications, and incisions in the acute affections

of the tonsils. He also corroborated what had been said regarding the evils attending chronic inflammation of the tonsils, and partially agreed with him regarding excision.

He was inclined to believe that follicular or herpetic tonsillar disease had simply a *different localization*, but was the same disease as inflammatory or membranous croup.

DR. D. B. ST. JOHN ROOSA remarked that the speaker was not willing to state positively whether the tonsil actually pressed upon the Eustachian tube, thus producing deafness, or not. He believed, however, that an inflamed tonsil never pressed upon the mouth of the Eustachian tube so as to cause deafness; but that the deafness, if present, was coincident, and depended upon inflammation of the mouth or calibre of the tube or tympanic cavity, caused by the same conditions as those which gave rise to the tonsillar affection. He was sorry for the introduction of the term "throat deafness," because it implied that there was a form of deafness dependent upon disease of the throat. In his opinion there was no deafness depending upon disease of the throat, unless the Eustachian tube or the tympanic cavity, as well as the throat, was involved. In acute tonsillitis he thought impairment of hearing very seldom was present, unless there was the history of a catarrhal deafness preceding the acute attack. He believed that we might have never so much swelling of the tonsils, and yet no impairment of hearing. Nevertheless, enlargement of the tonsils became an important factor in the treatment of diseases of the ear, and the ear could not be put into a healthy condition so long as such enlargement existed. Therefore, otologists were accustomed to advise excision of the enlarged tonsils, in order to favor obtaining a healthy throat, which so much favored a healthy ear.

With reference to gargling, he was in full accord with Dr. Leferts regarding its inefficacy; yet he believed it might be made much more efficacious than it ordinarily was, by following von Tröltzsch's method, which had not received the consideration to which it was entitled.

VON TRÖLTZSCH'S METHOD OF GARGLING.

The method is as follows: The gargle is held in the back part of the mouth, the head thrown well back, and the nostrils closed with the fingers; swallowing motions are then performed without actually swallowing the solution. That by this method the pharynx could be reached he had proven by painting the wall of the pharynx with iodine and then causing a solution of starch to be used as a gargle, when the characteristic reaction was produced invariably.

DR. R. P. LINCOLN remarked with reference to the wide influence which diseased tonsils, especially chronic hypertrophy, exerted over the ears, that it had been his fortune, in several instances, to see quite anomalous phenomena, which had led him to seek for a cause for ear-phenomena associated with tonsillar affections, and he had reached the conclusion that it was purely mechanical, and produced through the agency of the nerves coming from the glosso-pharyngeal, acting in a reflex manner. There was also, through the otic ganglia of the sympathetic system, a connection between the throat and the ear. Within the past week, in endeavoring to remove a collection of inspissated mucus from a tonsil, although it was done with the very least degree of violence, the patient subsequently suffered from pain in the ear sufficiently severe to prevent sleep, and yet there was

no manifestation whatever of inflammatory action in the ear itself. He thought such collections of inspissated mucus in the tonsils required treatment much oftener than, perhaps, ought to be inferred from the remarks of the writer of the paper. There were many patients who had enlarged tonsils, not perhaps to a degree to require excision, but often requiring treatment because of the pharyngeal catarrh they produced, and such cases he believed should be treated by applications, such as referred to, into the crypts themselves of the tonsils. Perhaps nitrate of silver might be used. A favorite mixture with him was carbolic acid and co. tr. of iodine, in the proportion of 1 to 2, applied directly to the lining membrane after the crypts had been rid of the collections of mucus. It was not always successful; and, when not, excising a small portion and applying the galvano-cautery to the lining of the crypt would almost always effect a cure.

He referred to a case in which a collection of inspissated mucus was as large as an English walnut.

DR. BOSWORTH believed that the exudation in follicular tonsillitis was croupous in character, and that it could be best cured by passing a probe coated with nitrate of silver into the crypts and the administration of large doses of quinine. With regard to the many evils attending enlarged tonsils, such as poisoned air going to the lungs, dyspepsia, etc., he was in accord with Dr. Leferts, but with reference to the sinking in of the bones of the chest and the formation of "pigeon-breast," referred to by Dr. L. as one of the results of enlarged tonsils, he should simply attribute that condition to a rachitic diathesis preceding and probably favoring the existence of enlarged tonsils. He also referred to nightmare as a common symptom of chronic enlargement of the tonsils.

With regard to *acute tonsillitis*, he thought it quite probable that, in most cases, no form of abortive treatment possessed special efficacy; still, in a number of instances he had succeeded in aborting what he believed was the disease by giving grs. x. of quinine, and following it with Fleming's tincture of aconite in such doses as would rapidly produce marked physiological effects of the drug, such as dryness of the throat, dizziness, and ringing in the ears, and then discontinue it. That method would do no good if suppuration had been established.

He regarded croupous, catarrhal, and diphtheritic as three distinct forms of inflammation, and thought that more care should be taken in making the nomenclature of diseases of throat to correspond to the pathological state.

DR. A. H. SMITH thought that incising the glands in *acute tonsillitis* left wounds nearly as large as would be made by ablation, and as the latter was the most efficient, it might better be employed at once.

With regard to occasional *failure of the stump of the tonsil to atrophy* after the projecting portion had been removed, it was perhaps to be explained, at least in some cases, that the tonsil receives blood at its upper portion, and the lower portion alone has been removed. If the upper portion of the tonsil was cut off, the supply of blood was removed, and the operation was quite effectual. If the anterior pillar of the fauces was adherent to the tonsil, as it was not infrequently, it was important to first break up the adhesions, so as to secure complete ablation of the superior portion of the gland.

He suggested the following method of *coating a probe with nitrate of silver*: Dip the extremity of the probe into powdered nitrate of silver and then hold it for an instant over a flame, and the silver that ad-

heres to the probe will melt and form a smooth covering.

Dr. F. A. BURRALL remarked, regarding the *treatment of tonsillitis*, that he did not accept the views of those who dissented from the use of *gargles*, because they do not reach the pharynx; for, as a rule, in tonsillitis it was not the pharynx we wished to reach. A gargle might be used so as to give pain, or it might be a temporary substitute for a poultice and give efficient relief. The action of a warm gargle repeated every half-hour was to favor suppuration, and, when they contained emollient substances, were very soothing and beneficial. Gargles, steam, and spray, all had their value. Stimulating gargles, were of value in reducing the size of hypertrophied tonsils. He favored constitutional treatment in throat diseases, and by preference gave a calomel purge in the early stages of acute tonsillitis.

All acute sore throats should be treated as if infectious, especially in children.

Tonics, beginning very early, and frequency of application, were very important in the abortive treatment of tonsillitis and other forms of sore throat.

REPORT OF THE STATISTICAL SECRETARY.

Dr. F. V. WHITE, Statistical Secretary, announced the death of Freeman J. Bumstead, M.D., LL.D., and gave a brief sketch of his life.

THE PRESIDENT paid the following tribute to his memory:

By the death of Dr. Bumstead, the Academy of Medicine and the profession of this city have lost one of its most eminent men, who contributed largely to give it the rank which is now conceded to it, not only in this country but abroad. He had always been a most industrious, methodical, able and honest worker for its science and its literature, and the results of his labors will hold a prominent and a permanent place in medical literature.

As an intimate acquaintance of more than twenty years, I am competent to say of his personal character, that it secured the warm affection and sincere esteem of all those who enjoyed this privilege.

In accordance with the by-laws, I will designate to prepare a memoir of Dr. Bumstead, one eminently qualified to do justice to his personal qualities, his professional abilities, and his literary work—Dr. GEO. A. PETERS.

ADOPTION OF NEW BY-LAW.

The new by-law relating to fellowship was adopted to take effect after the first meeting in January, 1880. The Anniversary Meeting was announced to take place on Thursday evening, December 11th, with Dr. Leroy M. Yale as orator, and his subject, "The Academy as an Educator."

The Academy then adjourned.

Anniversary Meeting, December 11, 1879.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

The Academy was called to order at 8 P.M., and prayer was offered by Rev. Dr. Washburn.

The orator of the evening, Dr. LEROY M. YALE, being unavoidably detained at home on account of sickness, Dr. F. A. CASFLE read the oration, which had for its subject

"THE ACADEMY AS A TEACHER."

A brief reference was made to the early history of the Academy in comparison with its present position in its new library hall, the munificent representa-

tion of the far-sightedness of one of the fellows; to the methods of controlling the education preparatory to entering the medical profession; to the great law of supply and demand, which had a marked influence in every department of society; to the principle that men, like water, found their true level—a principle which pretty constantly affected every member of society; and then the orator passed to the main subject of the oration, and inquired how had the Academy taught in the past, how is she teaching, and what part will she take in the teaching of the future?

The Academy had been efficient as a teacher in two important ways—namely, cultivation of the science of medicine, and elevation of the character and honor of the profession.

With reference to the first, the scientific papers presented during the thirty years it had existed, possessed considerable value; indeed, as had been said, "a value far greater than we can well imagine." It might be said that those old papers had been left far behind, and were worthless as aids to modern study; but their value must be estimated from the standpoint and the date at which they were written, and then their intrinsic worth became apparent, and the influence which they exerted upon the education of those who lived subsequent to their authors might be duly appreciated.

The second avowed object in founding the Academy was an ethical one, and that end had not been lost sight of. The loss of the esteem of the fellows was a potent factor in regulating the ethics of the profession, in elevating the character of its members, and maintaining its honor; and it was to be hoped that the influence of the traditions of the fathers would not be lost in this particular—namely, only those were elected to fellowship who won the position by purity of conduct.

The orator then referred to the library of the Academy, its origin and its work, and urged its claims upon the fellows and the profession for contributions of books, even old books—for it was nothing of disparagement to a library that it was rich in old books; and the calm wisdom of old experience was oftentimes more substantial aid than the brilliant exploits of young enthusiasm. The Academy had opened its reading-rooms, and the influence which a storehouse of books could exert might now permeate among the reading classes. But there were others whose wants should be supplied, and to that end he urged, with Dr. Thomson, who delivered the Anniversary Address for 1878, that lectureships should be established; and, in order to secure the lectures, if funds were not forthcoming, an appeal should be made to those who are able to lay aside their modesty and speak without pecuniary reward.

He also suggested the founding of scholarships, and asked if it was not possible for the Academy to found a museum. If museums were good, there could not be too many of them. To be sure, the city had Wood's Museum at Bellevue Hospital—a monument of great personal energy and industry; the New York Hospital Museum, and college museums. But the museums of hospitals and colleges would always be increased by those who were in close affiliation with them, while a museum founded by the Academy of Medicine would gather a new type of specimens, and a large amount of valuable material which now was wasted. A museum, once started, could be built up the same as had been the library, and all that could illustrate the science and art of medicine could be secured for the Academy, if it would undertake to be its custodian.

In conclusion, the orator alluded to the Academy as an association not devoted to special study or narrow special ends, but a common meeting-ground of the best elements of our professional body, and an organization that had the power of age and the character of authority.

The oration was well received.

THE PRESIDENT extended the thanks of the Academy to Dr. Castle, after which the exercises were closed by the benediction.

Correspondence.

THE EDITORIALS ON ASYLUM MANAGEMENT.

A LETTER FROM PROF. E. C. SEGUIN, M.D.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The issues of the RECORD for Dec. 6th and 13th contained editorial comments upon the Senate Committee's report on the petition of the New York Neurological Society, praying for an investigation into "the management of all institutions for the care of the insane in the State of New York." These editorials are calculated to cast discredit upon the members of the Society and upon the signers of the petition, and are based upon a confiding acceptance of the statements of the Senate Committee. This committee's report is biassed, filled with deceptive phrases, and contains positive falsehoods. This will shortly be made known to the public by the Neurological Society in a formal review of the report.

I now beg the privilege of calling your attention to a few points which may be of interest to your readers, and are necessary to a fair statement of the questions you raised.

1. You ought to have given the names of the committee of the Neurological Society, as a work is judged somewhat according to its authorship. The names of the committee which prepared the petition are: T. A. McBride, E. C. Harwood, E. C. Seguin, E. C. Spitzka, and J. G. Kiernan. After the acceptance of the petition by the Society, the names of William A. Hammond, W. G. Morton, and Landon C. Gray were added. These gentlemen are perfectly willing to be looked upon as petitioners in such a noble cause as that of bettering the condition of the insane. They need no defence, and fear no comparison with any one.

2. The committee of the Neurological Society believe to-day that every sentence of their petition is correct, and think that a thorough investigation made now would show that many of the questions in the petition would expose ugly sores. Was not the Asylum for Convicts at Auburn found in a frightful condition by a legislative committee in 1876, only three years ago? Yet that asylum had been approved by the officials who managed the proceedings of the Senate Committee (*vide* "Archives of Medicine," Vol. II., p. 190 *et seq.*). This instance (which reads like a story from asylums before the days of Pinel), and numerous complaints in the press, and our reading knowledge of the working of asylums, were the data calling for an investigation. Besides, we had material such as conversations with superintendents, long talks with assistant physicians, etc., which, being of a private nature, could not be utilized without breach of manners or of trust. But above this we deny that we were *witnesses*; we were citizens and taxpayers

praying for inquiry; we were *asking* for the facts from the only parties who could give them, viz.: the asylum officials, *under oath*. Dr. Willard Parker, Sr. (and no doubt others), wrote a letter of sharp rebuke to the Senate Committee, in reply to their "summons." They are careful not to print these letters. If we had had *charges*, in the technical sense, we would not have gone to the Legislature. What has it to do with "charges"? We would have gone to the Governor, or to the courts, with our charges and witnesses.

3. The Senate Committee, and I regret to say, the editorial also, ignore that in the very nature of the questions asked by our petition, ordinary outside testimony could not be adduced. For example, how can any one but a superintendent testify "of his own knowledge" as to the number of days he is absent from duty, the frequency of his night visits, his outside professional work, etc.

Indeed, I think that almost all the inquiries suggested by the petition are of such a nature as to be answered only in the way mentioned.

4. The Senate Committee speak as if our petition referred to *State asylums*. It did not; it expressly referred to "all institutions for the care of the insane in the State of New York." Several of the worst abuses we well knew not to exist in the State asylums.

5. In your first editorial, you speak as follows: "For this failure they are accountable to the profession they assumed to represent."

I would beg to know if, when you wrote this, you had seen the list of names attached to the petition? Did you know that the following gentlemen were petitioners?—Prof. Willard Parker, Prof. John T. Metcalfe, Prof. T. M. Markoe, Drs. E. R. Squibb, R. F. Weir, Andrew H. Smith. Why not say that these gentlemen *do* represent the profession; is it easy to find a more representative and honorable group? Such a statement as yours, like the insinuations of the Senate Committee about the motives of the promoters of the petition, and the standing of the Neurological Society, are personally offensive and unjust. As to the standing of the Society, your own columns for the past two years are good enough witnesses.

6. Next, as to a vile charge circulated broadcast by the superintendents and the Senate Committee: that of forging names of signers. President Barnard did sign the petition (my own copy) without solicitation, after keeping the document at least three days. He simply forgot all about it, and then wrote letters of a most injurious tenor. I called upon Dr. Barnard in April about this matter, and found his *amnesia* still complete. He then said that his reason for withdrawing his name from the petition was that it affected the reputation of a colleague and friend (the Commissioner of Lunacy), and he expressed no criticism of the petition itself. So the name of Dr. John W. Draper was forged! It happens that the name on the petition is John C. Draper; no one sought to obtain his father's name.

7. Your second editorial seems to have been written with quite another kind of ink. It also treats the petitioners unjustly, but in some respects it encourages us. In it you express substantially our grievances, you proclaim the existence of abuses, and (most comforting) you do it precisely as we did it, without legal proof. If a power were to place you on the witness-stand, could you "of your own knowledge" testify as to the existence of the abuses you write about? We must, indeed, pity the insane if their treatment is to be improved only after legal

proof of mismanagement, neglect, non-medical treatment, etc., is obtained.

I would conclude by saying that the petitioners are in no wise on the defensive, but are as active as ever for asylum investigation and reform. Some of them were glad to co-operate in the movement which culminated in the meeting at Cooper Union on December 18th. They will be satisfied if a lunacy commission or board of lunacy be established, for one of the duties of such a board will be investigation. I greatly fear that next winter will witness an opposition to the bill for a commission—an opposition conducted by the asylum officials. Yet, the other evening, the Rev. Dr. Storrs reminded the superintendents, that their safety and good reputation would only be made more secure in public estimation by having such a commission, and by answering all questions. As he eloquently said, the broad light of day should shine upon this whole subject of lunacy.

Very truly yours,

E. C. SEGGIN.

[THE strictures of our esteemed correspondent invite a word or two of explanation from us. At the start we put in a plea of not guilty. We are sorry to say that we have nothing to retract. The true significance of this assertion will be better understood, perhaps, when we state that we are in full sympathy with all well-directed methods for reforming asylum management. We candidly confess that we expected better things of the Neurological Society. In the expression of our disappointment at the results of the petition, we believe we echoed the general sentiment of the profession. If we have misinterpreted such a sentiment we are willing to acknowledge our error.

Our remarks were based, it is true, "upon a confident acceptance of the statements of the Senate Committee," because we had nothing else to guide us. We were not aware, at the time of writing, that the report of the Senate Committee was biased, etc., and even now we are asked to wait for the proof of such a charge until the committee of the Neurological Society shall make a formal review of said report.

We did not mention any names in referring to the petitioners. In the discussion of principles, we can afford to lose sight of individuals. We were estimating the character of the work rather than the ability of the workers. We acknowledge their ability, but are simply disappointed in their work. There is no disposition on our part to deny them the privilege of petitioners. They are working in a good cause, and we hope they will be able in the forthcoming report to vindicate their course in the recent investigation. We did not assert that the gentlemen who were witnesses before the committee could not prove that there were very many abuses in asylum management, but that they did not.

We are not a little surprised to learn that, after testifying before the committee, the gentlemen must not be considered as witnesses. If it were not proper to appear as witnesses, why did the gentlemen do so? But we are not willing of ourselves to acknowledge that they did wrong, under the circumstances, in simply appearing and in giving testimony. The petition was an extraordinary one, in that it referred to gross abuses in the medical management of insane asylums, and the Senate Committee very naturally asked for some explanation from the medical men signing the petition. The end to be attained was of such great importance that the petitioners were warranted in giving all the aid they could to the Senate Committee. When the Senate Committee

state that the petition refers simply to State asylums, they are clearly in error. But we cannot understand what this has to do with the question.

Evidently, there were many questions which could not have been answered by any but the superintendents or nurses of asylums; but, besides, there were statements of the greatest possible significance referring "to more strictly medical matters," which should have been verified by the petitioners themselves. This was all that could have been expected of them.

In the matter of accountability to the profession, we referred more particularly to those gentlemen who appeared as witnesses, and to those who were the more active movers in the petition. If the other petitioners, named by our correspondent, are willing to endorse all that has been done by their confrères before the Senate Committee, we are of the opinion that they likewise are accountable to the profession. In fact, the higher and more representative their positions, the greater are their responsibilities.

We did not know, when we wrote the editorials, who were the additional signers referred to by our correspondent. Hence we are entirely innocent of any charge of ignoring their representative character, or of applying any remarks to them which were "personally offensive and unjust." But we fail to see how a mere knowledge that these particular gentlemen had signed the petition could have helped us to any different conclusions. We said nothing against the standing of the Neurological Society. The very fact that the petition was endorsed by the Society and started by some of its prominent members, gave us every hope that great things would be accomplished.

We have nothing whatever to do with the so-called charge of forging names to the petition. We never believed such a thing possible with any member of the committee, and any explanation referring to it is entirely irrelevant to the discussion. We claim that the second editorial referred to by our correspondent was perfectly in keeping with the first. We have often written of the abuses in asylum management, and there is nothing inconsistent in referring to them in connection with the report of the Senate Committee. Our statements are always founded on facts, and we are always ready to assume all responsibility for them. If we cannot furnish legal proof for everything we say concerning asylum or other matters in these columns, we are willing to publicly retract such statements and apologize besides for our presumption.

In conclusion, we beg the pardon of our correspondent for replying to him in this direct manner; but we could not deny him the justice of being heard, neither could we afford to have many of his statements go unchallenged.—G. F. S.]

KOLPOKLEISIS AND CLOSURE OF THE VULVA FOR VESICO-VAGINAL FISTULA.

REPLY TO DR. WM. GOODELL.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In your issue of Nov. 29th, under "Reports of Hospitals," are set forth the views of Dr. William Goodell upon the treatment of twenty or more of the diseases of women as they have occurred in his service at the Preston Retreat, Philadelphia. Prominent among them are kolpokleisis and "closure of the vulva for vesico-vaginal fistula."

Dr. Goodell's deservedly eminent position, both as a teacher and a writer upon gynecological subjects, gives his views and opinions great weight with the

profession, whether endorsed or not by the individual reader.

I am induced to call special attention to Dr. Goodell's method of treating certain forms of vesico-vaginal fistule, by asking two questions: First, is the method he recommends the best that can be employed? and, second, does it have the sanction of American gynecologists?

1. *Is the method recommended the best that can be employed?*

Upon this point, Dr. Goodell is reported in these words: "In curable cases of vesico-vaginal fistula, in which the urethra has been destroyed, he has twice succeeded in wholly relieving the patient. In one instance this was done by making an artificial recto-vaginal fistula; and, in the other, by leaving an already existing one intact, and closing up the vulva. Whenever practicable, he prefers, in this unfortunate condition, when the urethra is unimpaired, to close the vagina as high up as possible, so that the marital relations shall not be interfered with."

Now, with regard to the destruction of the urethra, from whatever cause, when associated with an incurable vesico-vaginal fistule, the teaching of Dr. G., if the writer understands it properly, is to establish a permanent fistulous opening between the rectum and vagina, should one not already exist, and then proceed to close up or obturate the vulva by refreshing and uniting with sutures both pair of the labia pudendi, thus throwing the bladder, vagina, cavity of the uterus, and rectum into direct communication with the anus, which shall serve as a common outlet for all. The effect of this is to force all the urine to pass from the bladder into the vagina, and from the latter into the rectum, alone or commingled with the menstrual blood when present, and *vice versa*, the gas and dissolved feces to pass from the rectum into the vagina, thence into the bladder and the cavity of the uterus, when, as is usually present in this condition, a patulous condition of the mouth of the latter favors it. To this state of things the gradually developing sequences must also be added—such as alkaline urine, cystitis, nephritis, calculous formations in the kidneys, ureters, and bladder, vaginitis, with calculous formations and ulcerations, granular erosions of the os uteri, endometritis, metritis, cellulitis, peritonitis, nervous complications, irritation, inflammation and ulceration of the mucous coat of the rectum, chronic diarrhoea, gradual loss of power over the sphincter ani muscle, with more or less incontinence of the urino-menstrual secretions with the feces; death sooner or later, and the picture of the ordeal through which the sufferer may be expected to pass is complete.

Scarcely need it be said that this is kolpopleisis in its worst form. Even when the urethra is uninjured, and the object is to refresh and unite the opposing walls of the vagina high up, for the relief of incurable vesico-vaginal fistules, and as a means of preserving the sexual functions, as stated in the quoted remarks, the accompanying sequences differ only in number, and the sufferer will have to pass through the same ordeal indicated above, less that portion relating specially to the rectum and its functions. Dr. Goodell's large clinical experience may enable him to draw more hopeful conclusions in the classes of cases pointed out than is here shown by the writer; but the laws of chemistry, and those affecting the spread of disease, whether in the solid textures of organs or in their hidden cavities, are invariable; and from what has already been abundantly attested in these particulars by equally close observers, there

is reason to believe he, too, will have occasion, sooner or later, to change his views regarding results, should he chance to watch these cases long enough, and interpret aright the concatenation of sequences just enumerated. To convert a part of the vagina into a urinal, as by kolpopleisis, to relieve incontinence of urine, and to save the other part, "so that the marital relations shall not be interfered with," while the urethra serves as an escapement for the urine and menstrual blood, is acknowledgment enough of the defectiveness of the resources of gynecology; but to feel obliged to make not only an urinal, but a gasometer of the vagina and bladder, as by vulvopleisis with the rectum serving both as supply and escapement tube for gas, feces, menstrual blood, and alkaline urine, is still more humiliating in the face of so many advanced improvements in other special branches of practice. This writer is of the opinion that in all cases calling for such methods of treatment, a plug-valve and an overflow escapement are far preferable, and that the place for the former is in the recto-vaginal passage, and, for the latter, in the mouth of the vagina. He furthermore believes, these two points of practice being recognized and insisted upon, that if the resources of gynecology are not equal to the requirements of overcoming the obstacles to the legitimate cure, with preservation of all the normal functions intact, it is better to trust to mechanical expedients by which the free outlets of the bladder, vagina, and uterus can be maintained, and the sufferer made in no small degree comfortable and contented.

The analogue of the perversion of the functions of the rectum as above indicated, is found to exist in the male subject from the establishment of a communication between the rectum and the bladder—recto-vesical fistule—from whatever cause; but in this relationship of the two organs, the bladder maintains its urethral escapement, by which it is siphoned both of gas and urino-faecal discharges. It differs in this last important particular from the female bladder after the employment of the method described, since the urethra is here supposed to be destroyed and its vacant place shut in, thus rendering it impossible through this natural channel to siphon either the bladder or vagina of gas and urino-menstrual and faecal fluids.

Now the evil consequences of a recto-vesical fistule are almost nothing as compared with those following a recto-vagino-vesical fistule, yet where is the surgeon to-day, with the bright lights of science dazzling before his eyes, who would dare imitate the example of Sanson (1816), and cut for stone through the rectum, with nearly all the chances against him that the lesion in question, with all its dreaded sequences, would follow? Great, however, as the responsibility would here seem to be, it is but little, if any, less great than the employment of the method under consideration, without a compensating urethral escapement, with stop-cocks by which the bladder and vagina might, at least, be siphoned occasionally of their constantly accumulating gas from the rectum, and be flushed in their deep pouches and recesses with disinfectants.

2. *Has the method recommended received the sanction of American gynecologists?* In 1833, when Vidal (de Casis) first proposed to obturate the vulva for the relief of incontinence of urine from vesico-vaginal fistules situated in the *bas fond* of the bladder, and attended with loss of tissue, then believed to be incurable, as shown by various discussions upon the subject before the Academy of Medicine of Paris, it did not

occur to him that closure of a mutilated urethra or its vacant place might ever be included in the same novel procedure. To whom the credit is due of having been the first to execute this modification of the procedure of M. Vidal, the writer is not informed. Per contra, from the great improvements made in the treatment of vesico-vaginal fistule within the last few years, the writer had supposed that this French theory had sunk into desuetude. Having himself only one time, many years ago (1853), attempted the expedient, which failed, in a case thought to require it by an eminent gynecologist, and having afterward legitimately cured the case with preservation of the functions of all the organs involved, he can now hardly be expected to set any higher value upon the modification of it here discussed, than upon the original procedure at the date mentioned. As to the appreciation of American gynecologists generally of such expedients, he has again to acknowledge his want of information. Dr. T. A. Emmet, in his recent work (Principles and Practice of Gynecology), may, however, be referred to as having lately ranged himself on the side of opposition to kolpopleisis, the twin sister of the procedure under consideration. After speaking in a general way of the controversy between the author of this method and the writer, he says: "There exists no greater malpractice in surgery than the procedure which we are told was practised by that great master, the late Prof. Simon, of Heidelberg." In the interest of suffering women, no more important precept in practice than the above could be laid down for the guidance of inexperienced operators, and of itself is enough to recommend the author, although at the eleventh hour, to the highest consideration, even had his book no other claim to merit. Now, notwithstanding the fact that the writer has for so many years stood alone, and opposed, upon scientific grounds, these French and German expedients, both with his pen and upon the operating-table, at home and abroad, under the eyes, so to speak, of their authors, he has never yet characterized them as malpractices; he has, however, often said, and here reiterates it, that they have a most important medico-legal bearing, both as regards the marital rights of husbands and the recourses left to mutilated and helpless wives, that will, sooner or later, in extreme cases, demand, he believes, judicial investigation as to the legitimacy and necessity of their employment. While kolpopleisis, especially, is known to be notoriously common throughout Europe, except, perhaps, in Austria, arising, mainly, from a want of appreciation of kolpocoeptasis, its opposing companion here in the United States, where the first highest success in the treatment of vesico-vaginal fistule was attained, the latter principle, in some form, has generally been accepted and acted upon, though oftentimes, no doubt, very inefficiently. The consequence is, that the objectionable expedient herein has been kept in the background which only occasionally comes to the front under some other designation than Kolpopleisis, as may properly be said of the words quoted in the sentences forming the basis of these remarks.

A rose is said to be just as sweet called by any other name. The closure of the vagina in its continuity, by agglutination of its walls, for an incurable vesico-vaginal fistule so-called, is high-sounding, it is true, to the uninformed and uninitiated; and the proposal really does at first glance betoken some science and philosophy, especially to have coupled with it the assurance "that the marital relations shall not be interfered with." But, however that may be, the

vindication of science or of philosophy, it is believed by the writer at least, accepts the old cognomen kolpopleisis, which openly contemplates the establishment of a urinal in one end of the vagina, and a blind *cul-de-sac* of variable dimensions in the other end, as far preferable, since it is historic; and he or she who reads it aright may understand its worth, the ignorant as well as the learned.

Yours truly,

NATHAN BOZEMAN, M.D.

NEW YORK, Dec. 8, 1879.

DR. JOHN C. PETERS AND THE TRANSACTIONS OF THE NEW YORK PATHOLOGICAL SOCIETY. — In our recent review of the Transactions of the New York Pathological Society, we accidentally omitted mention of the name of the editor, Dr. John C. Peters, to whom all the credit is due for making the volume what it is — the most interesting and instructive of its kind yet published.

LUMBO-COLOMOTOMY. — Dr. Howe's case of lumbo-colotomy lived seven months, instead of seven weeks, as stated in the report of the Pathological Society.

THE SUCCESSFUL PRACTITIONER OF PINE RIDGE. — To such as may be interested in the success of the "Successful Practitioner," we will state that his letters have been so extensively copied in the various journals over the country, that he has become concerned about his reputation.

The following letter to the *Boston Medical and Surgical Journal* proves that the best of us are anxious to be right on the record. It also affords us another example of the practitioner's kindness towards White and his concern for the Code. His reply to a complimentary letter from France shows him ever ready to be obliging:

To the *Boston Medical and Surgical Journal*:

"Mr. Editor — Although my great professional success has placed me beyond any vanity for new triumphs, I cannot help expressing my satisfaction in seeing my letters republished 'in your excellent, influential, and widely circulated journal.' I hope that the foregoing compliment will permit me to 'call your attention to an error of your printer.'

It so happens that, very unfortunately for my reputation in this country and abroad, you call me the 'Pea Ridge' instead of the 'Pine Ridge' practitioner. The fact is, my former partner lives at Pea Ridge, and is making capital for himself by claiming to be the author of my letters. I have heard, incidentally, that many patients really sent to me have

come under his care in consequence of your error. This would be a small matter, as I did not write to advertise myself, but in justice to 'my noble profession, of which I am an humble member,' I believe it to be my duty to expose fraud.

I may say, in passing, that White is growing a little cool towards me. I cannot imagine the reason for this, except that I now have another of his good families. I was called in consultation a month ago, and heard nothing more of the case until the father of the family asked me to be the regular attendant henceforth. I at first refused, and told him of code regulations, when he said that he had really discharged White; that it was a free country, and he was determined to have a doctor to suit himself. I smilingly said, 'there was no accounting for people's tastes,' and rather reluctantly consented to oblige him. I felt it my duty, however, to say a good word for poor White, by remarking that, notwithstanding almost all his patients eventually came to me, I really pitied him. He deserved better things. I saw, however, that my new patient did not care to sympathize with me, inasmuch as he said he believed in the survival of the fittest. But it only shows how ungrateful patients can be.

Please give my compliments to your friend in Pau, France, and tell him that when he returns to this country I should be happy to meet him in consultation. I intend to send him a copy of the latest edition of my work.

If it is not asking too much, you may mention in 'your valuable journal' that I have been elected trustee of our college, and that the class is larger than ever this year. Also, that I have performed my nine hundred and seventieth operation for abrasion of the os, and am just completing the fortieth edition of my work, which will be immediately translated into all the foreign languages. When you receive the work for review, be careful not to send it to my partner at Pea Ridge.

* * *

LINE RIDGE ON THE HUDSON.

LISTER IN GERMANY.—The French know how to say things effectively. M. Verneuil, in commenting on the enthusiasm with which the Lister treatment has been received in Germany, says: "In Germany the antiseptic treatment is not a method; it is a religion, and a religion which has its priests—and also its martyrs." Lister has taught the Germans surgical cleanliness; for this, if not for his theories, they should be grateful.

METALLOTHERAPY.—Five cases of paralysis are said to have been cured recently by the external application of magnets. The cases were not all hysterical ones. The first had been poisoned by lead; the second was subject to epilepsy; the third had had an apoplectic attack.

MM. Proust and Ballet are the gentlemen who announce these cures. They have made reports before, and their statements grow more wonderful with each report.—*Gazette Méd. de Paris*.

HYSTEROTOMY IN THE TREATMENT OF FIBROUS TUMORS.—M. Duplay has communicated to the French Academy of Medicine some statistics in regard to the treatment of fibrous and fibro-cystic tumors by operative procedure. He divided the cases into those of fibrous and those of fibro-cystic tumors of the uterus.

1st. Of fibrous tumors that had been removed by laparotomy, leaving the uterus behind, there were 17 cases, with 5 cures and 12 deaths. Similar tumors

removed with the whole uterus, 55 cases—23 cures and 32 deaths.

2d. Of fibro-cystic tumors, 41 cases, with 22 cures and 19 deaths.

Uniting the whole, there are 113 laparotomies for fibrous tumors, with 50 cures and 63 deaths.—*Gazette Hebdomad.*

THE PRECURSORS OF CANCER.—At a recent meeting of the London Clinical Society, Mr. G. Lawson read the notes of a case of cancer of the breast following eczema of the nipple. In the subsequent discussion a number of prominent surgeons took part, including Sir James Paget and Mr. Hutchinson, and some interesting facts were brought out. It was pretty generally agreed that there were a number of chronic disturbances of nutrition, which, if neglected, ended in cancer, when the cancerous period of life came on. Thus, eczema of the breast, if it were really eczema, was shown in a certain per cent. of cases to be a precursor of cancer, and the question of the early extirpation of the breast was a very important one. A similar clinical history was ascribed to ichthyosis of the tongue. This, in course of time, is likely to eventuate in cancer. A like remark applies to old burns or scars on the lower extremity. If, in advanced life, these begin to ulcerate, they are liable to become cancerous. So, too, of other conditions, such as syphilitic disease of the tongue.

The importance of knowing that cancer has its precursors was strongly urged, and an early treatment advised.

FUCUS VESICULOSUS.—This plant has now become quite popular as an anti-fat agent. In connection with its supposed properties in this direction, the *Medical Press and Circular* relates the history of its use by Laënnec fifty years ago. Laënnec had observed that on the coast of Brittany there was very little consumption. Attributing this to the atmosphere of that country he tried to reproduce it, as nearly as possible, in his wards in Paris. He had a quantity of sea-weed, including the fucus, brought to his hospital and placed near the beds of his phthisical patients. He also made them drink an infusion of the *fucus vesiculosus*. As long as the patients had the fresh plants, much improvement in health was noticed; cough and fever diminished, and the weight increased. It thus appears that the *fucus*, which is now used to reduce the weight, fifty years ago was used to increase it! Perhaps one may be permitted to exclaim: *O tempora! O mores!*

GALVANI.—A monument has recently been erected in Bologna to Luigi Galvani. Signor Vella, Bolognese Professor of Astronomy, in a memorial address took occasion to defend vivisection very eloquently.

BENZOATE OF SODA.—The number of diseases for which benzoate of soda is a specific, or claimed to be, is increasing at the rate of about one every two months. Starting as a cure for diptheria, it has had like claims for it in scarlatina, acute rheumatism, and puerperal fever. Now Rokitansky is said to have discovered anti-tuberculous virtues in it. As the pathology of consumption is reverting to the tubercular basis, the drug has been tried in that disease, and with reputed great success. A five-per-cent. solution is sprayed down and into the bronchial tubes twice a day.
